Sara Miller McCune founded SAGE Publishing in 1965 to support the dissemination of usable knowledge and educate a global community. SAGE publishes more than 1000 journals and over 600 new books each year, spanning a wide range of subject areas. Our growing selection of library products includes archives, data, case studies and video. SAGE remains majority owned by our founder and after her lifetime will become owned by a charitable trust that secures the company's continued independence.

About the Editors

Abbie E. Goldberg is Professor of Psychology and Director of Women's and Gender Studies at Clark University in Worcester, Massachusetts. She received her PhD in clinical psychology from the University of Massachusetts Amherst. A central theme of her research is the decentering of any "normal" or "typical" family, sexuality, or gender, to allow room for diverse families, sexualities, and genders. For 15 years, Dr. Goldberg has been conducting a longitudinal study of adoptive families headed by female, male, and heterosexual couples. Dr. Goldberg also conducts research on the higher educational experiences of trans and gender-nonconforming individuals. She recently completed a longitudinal study of postpartum well-being in women with diverse sexual histories. She is the author of over 120 peer-reviewed articles and three books: *Lesbian and Gay Parents and Their Children: Research on the Family Life Cycle* (American Psychological Association, 2010), *Gay Dads* (NYU Press, 2012), and *Open Adoption in Diverse Families* (Oxford University Press, 2019). She is the coeditor (with Katherine Allen) of *LGBT-Parent Families: Innovations in Research and Implications for Practice* (Springer, 2013; 2nd edition 2020) and the editor of the *SAGE Encyclopedia of LGBTQ Studies* (SAGE, 2016). She is also the coeditor (with Adam Romero) of *LGBTQ Divorce and Relationship Dissolution* (Oxford University Press, 2019). Her books have received numerous awards. She has received research funding from a variety of sources, including the American Psychological Association, the Alfred P. Sloan Foundation, the Williams Institute, the Society for the Psychological Study of Social Issues, the National Institutes of Health, and the Spencer Foundation.

Genny Beemyn is the director of the University of Massachusetts Amherst's Stonewall Center and the coordinator of Campus Pride's Trans Policy Clearinghouse. Genny has published and spoken extensively on the experiences and needs of trans college students, including writing some of the first articles on the topic. They have written or edited 11 books/journal issues, including *A Queer Capital: A History of Gay Life in Washington, D.C.* (Routledge, 2014) and *The Lives of Transgender People* (Columbia University Press, 2011) with Sue Rankin. Genny's most recent book is an anthology, *Trans People in Higher Education* (SUNY Press, 2019). They are currently writing *Campus Queer: Addressing the Needs of LGBTQ+ College Students* with Mickey Eliason for Johns Hopkins University Press. Genny is also an editorial board member for the *Journal of LGBT Youth,* the *Journal of Bisexuality,* the *Journal of Lesbian Studies,* and the *Journal of Homosexuality*. They have a PhD in African American Studies and master's degrees in African American Studies, American Studies, and Higher Education Administration.

Introduction

Trans people's lives, experiences, and perspectives are increasingly visible in society, yet rarely centered. Educational, health care, and legal systems, for example, have historically been deeply and fundamentally grounded in a gender binary and have focused on and reflected the needs and experiences of cisgender (cis; non-trans) people. Trans people have challenged this centering, pointing to the psychological, social, and physical harm it has created and perpetuated not only for trans people but for all people. Gender normativity, cisgenderism, and transphobia are fundamentally destructive forces in institutional, interpersonal, and intrapersonal domains. By contrast, gender inclusion, gender creativity, and trans affirmation have transformative potential, with the power to advance personal and societal liberation and resilience when they are centered in institutional, political, and social policy and practice.

The SAGE Encyclopedia of Trans Studies centers trans people and experiences across a wide range of disciplines. Scholarship about and by trans people has proliferated over the past few decades, in fields as diverse as history, education, sociology, film, literature, and medicine. In turn, the encyclopedia is a multidisciplinary and interdisciplinary collection with more than 300 entries. This encyclopedia aims to capture the "state of the field," covering broad areas and concepts (e.g., cisgenderism, health care discrimination, mental health), as well as more narrow and specific topics (e.g., chest feeding, geek culture, the military and military ban, social media influencers, sororities and fraternities). It covers organizations (e.g., interACT: Advocates for Intersex Youth, Lambda Legal, Transgender Law Center, World Professional Association for Transgender Health [WPATH]), people (e.g., Harry Benjamin, Chaz Bono, Jazz Jennings, Sylvia Rivera, Lou Sullivan), and events (e.g., Compton's Cafeteria Riot, Stonewall Riots) relevant to trans people. Its coverage emphasizes and is infused by an intersectional perspective, whereby trans identities and issues are considered in concert with other identities and social positions, including race, sexuality, and locale. For example, we have entries on Asian Americans, asylum, Black people, fa'afafines, immigration, Indigenous people, Latinx people, māhū, neurodiversity, racialized femininities, and racialized masculinities. We also aimed to capture the considerable diversity within and across "trans" by including entries that explore the vast array of identities and expressions under the trans umbrella. For instance, the encyclopedia covers agender people, crossdressers, drag kings, drag queens, nonbinary genders, and two-spirit people.

As editors, we aimed to consider trans people's experiences in diverse contexts and systems (family, workplace, school, legal, health care, child welfare) as well as across different life stages (youth, adulthood, older adulthood) and transitions (puberty, pregnancy, parenthood, death). We also center trans people's relationships, such as those with siblings, parents, partners, children, and mentors. In addition, we address key concepts and constructs (e.g., embodiment, feminism, resiliency, transnormativity), methodological issues (e.g., measurement issues, qualitative research, intersectionality in research), and debates (e.g., conversion therapy, gatekeeping in the transition process, religious acceptance). Other areas we examine are trans people's contributions to the arts (e.g., Canadian and U.S. artists, fiction, film, musicians, poetry) and to sports (high school, college, professional).

Some distinctive features of this reference work include the array of disciplines and approaches (conceptual, theoretical, applied, historical) represented and the inclusion of a wide range of contributors, including professionals in the field,

academics, activists, and writers. The text also benefits from often having entries written by the people behind the topics (e.g., the Trans Pride Flag entry was written by its creator; the entries on the Transgender Day of Remembrance, the International Day of Transgender Visibility, International Pronouns Day, and the International Conference on Transgender Law and Employment Policy were written by the founders of these events). In addition, almost all of the entries on trans and trans-supportive organizations (e.g., the American Civil Liberties Union, GenderPAC, Lambda Legal, the National Center for Transgender Equality, the Sylvia Rivera Law Project, the Transgender Law Center, the Trans People of Color Coalition, Transexual Menace, Tri-Ess) were written by leaders or former leaders of these groups.

Terminology

To have consistency across the encyclopedia, we asked contributors to use *trans* as an umbrella term for all individuals whose gender identity/expression is different from their sex assigned at birth, and thus *trans* includes both binary (e.g., trans women, trans men) and nonbinary (e.g., agender, gender fluid, genderqueer) gender identities. This definition is important, because nonbinary people are excluded from being "trans" by the growing use of the phrase "trans and nonbinary." Similarly, the increasing use of "trans*" as a way to be visibly inclusive of nonbinary gender identities has the effect of limiting "trans" to binary individuals. To further ensure that the diversity of gender identities was not ignored, contributors were asked to specify "nonbinary trans people" or "binary trans people" (or, in some cases, "trans women" or "trans men") if they were referring to the experiences of only one part of the trans community.

To respect the gender identities of the people profiled and cited, the contributors use the pronouns used by the individual. For historical figures whose pronouns are not known, the pronouns that best seem to fit their identity are used. Contributors were also asked to use the pronouns associated with a person's gender identity even when referring to their lives before they came out and socially or medically transitioned, as we recognize that many trans people see themselves as having always been gender nonconforming and self-identify before they disclose to others.

Background of the Encyclopedia

We, the editors, come from different disciplinary backgrounds (social sciences, humanities, and education), hold different professional roles (professor, administrator) at universities, and have a complementary set of research interests, skills, and professional and personal contacts. We began the background work for this encyclopedia by conducting online and personal bookshelf searches for texts on various topics related to trans studies. We sought to compile a list of potential topics that was not only representative of the field today but also cutting-edge and anticipatory of future research directions. As a result, there are topics about which a fair amount has been written (e.g., health care discrimination, misgendering) as well as topics that are newly emerging or long understudied (e.g., trans DIY, transmisogynoir, veterans). In determining what ground we would cover, we also sought to emphasize trans experiences across the life cycle, intersections between gender and other aspects of identity, and key contexts and systems that affect trans lives.

After establishing a nearly complete list of potential entries, we solicited further feedback from editorial team members and colleagues and also asked for their thoughts on potential authors for entries. We sought out accomplished researchers, scholars, and practitioners with established expertise on the given topic of the entry. The majority accepted, and some offered to write multiple entries. Some chose to enlist the help of coauthors, such as advanced doctoral students.

Invitations to contribute were sent out beginning in August 2019. The majority of authors were asked to revise their entries at least once. By August 2020, we had received final versions of all entries. The editorial team worked quickly and carefully, delivering feedback in remarkably little time, especially at the tail end of the project, when we had only a few remaining entries to review and edit. We are amazed at what has been accomplished—by authors and the editorial team—in just over 1 year. Indeed, many entries were due in February and March 2020—coinciding with the outbreak of COVID-19 and the upending of

many of our lives. This upheaval was amplified in the spring and summer, when the need to organize against police violence and demand racial justice in the United States and across much of the world added to the disruption and stress caused by the pandemic. Several editorial team members and a number of contributors withdrew their participation, and some entries were not finished by their original deadlines or even by revised ones. But most contributors persevered, and we are extremely grateful that they saw the value of this project to such an extent that they stayed with it and completed their work despite the obstacles. To say that this book was executed and completed under challenging circumstances is a tremendous understatement. Yet we are delighted with the final product.

The Audience

We want undergraduate students to be able to use this volume. We also want graduate students and scholars whose work centers on or includes trans experiences to learn from this encyclopedia. We would like policymakers and activists to draw on the many important topics in this encyclopedia as well, using it as the basis for their transformative work. We are hopeful that scholars in law, psychology, anthropology, history, family studies, social work, counseling, medicine, and other fields—who may know little about many of the topics—will read and incorporate the information into their thinking, writing, and teaching. We are hopeful too that librarians and other university staff and administrators will find this collection to be a useful and interesting tool for advancing their own understanding of these issues and for informing the work that they do. And importantly, this book is for trans individuals who are seeking a resource where they are at the center of thinking, theorizing, and research, instead of at the margins.

Organization of the Entries

Topics are in alphabetical order, from Academia to YouTube. Some topics are far-reaching and multifaceted (e.g., activism, discrimination, mental health) and thus are addressed in multiple entries. Long entries (those that are about 3,500 or 5,000 words in length) are broad in their conceptual scope and cover significant and well-researched topics in the field. Medium-length entries (about 2,000 words) address topics that are narrower in scope or about which less research has been done. Short entries (about 1,000 words) focus on a specific issue, person, or organization or describe a newer topic in the field. Appendices list important archives, journals, websites, books, and articles in trans studies.

Acknowledgments

This project reflects the contributions of many. Andrew Boney, the acquisitions editor, worked with us to develop the initial idea for the encyclopedia. His enthusiasm and commitment to this project helped to launch the project into reality. Sanford Robinson, our development editor, was thoughtful, patient, and conscientious, with scrupulous attention to detail as well as the "big picture." He helped us to stay on track even when the world seemed to be caving in around us. Leticia Gutierrez helped to ensure that SAGE's Reference Tracking system was working for both editors and authors and frequently came to the aid of the editorial board members when we had a question we could not solve on our own. We are also deeply grateful to the editorial team. Tre Wentling and Emily Skidmore, a sociologist and historian, respectively, complemented our expertise and backgrounds in important ways that deepened and nuanced the final product. They suggested contributors, provided constructive and timely feedback to authors, and maintained their commitment to the project despite the global pandemic.

We are very grateful to the colleagues who provided suggestions about potential topics and authors and who helped to fill in the gaps of our own knowledge when needed. Special thanks go to Gavi Ansara, Elizabeth Boskey, Amy Brainer, Finn Enke, Kale Fajardo, Paz Galupo, Ruben Hopwood, Rhea Hoskins, Sabra Katz-Wise, Katherine Kuvalanka, and Carla Pfeffer.

We are also very grateful to the trans activists, researchers, and writers—both living and dead—whose tireless work on behalf of the trans community made a volume like this possible.

Abbie E. Goldberg and Genny Beemyn

A

Academia

Academia is a term for the environment or community where individuals and groups pursue research, scholarship, teaching, and learning. Academia typically refers to activities that occur within colleges and universities and is both a physical location and a sociocultural production—that is, processes that generate norms, practices, and values. While there is much variability within academic organizations within the United States and beyond, across these varied organizational contexts, there are common components, such as being home to fields of study; a hierarchy among students, faculty, and staff; and the multiple missions of academic organizations.

Academia is an important location for knowledge production about trans lives and experiences, although it is not the only source of such knowledge. Additionally, academia is a space for trans community building. Yet, many trans students, faculty, and staff have negative experiences within academia. As a result, academia is a site of both possibility and constraint for trans people. Possibilities for trans people within academia center on two primary areas: knowledge production and policies and practices. Constraints for trans people within academia derive from the presence of multiple systems of oppression and uneven efforts to address the needs of trans faculty, staff, and students. This entry explores the growth of both possibilities and constraints for trans people within academia, specifically addressing the duality of trans knowledge production and trans-affirming policies and practices.

Possibilities Within Academia

Knowledge Production

Academe holds much possibility for trans people, primarily through knowledge production about trans lives in traditional disciplines like psychology and medicine and in interdisciplinary fields like public health, women's and gender studies, and trans studies. Across areas of study, the development of scholarly communities within academia has increased knowledge about trans lives and led to trans experiences being addressed in affirming, life-giving ways. Faculty members, in concert with student activists, have created space for trans-supportive knowledge production, such as through advocating for archives, journals, and academic departments.

Various fields of study benefit from trans archival and library resources. The largest collection is the Transgender Archives at the University of Victoria in Victoria, British Columbia, which began in 2007 and consolidated various collections, including the Reed Erickson collection and the University of Ulster's Transgender Archive. Other important collections include the University of Michigan's National Transgender Library and Archives, which was dedicated in 2004, and the Digital Transgender Archives, which began in 2016 and was based at Northeastern University as of 2020. Additionally, some universities, like the University of Houston and Cornell University, have LGBTQ+ archives with significant trans content. These repositories have been instrumental in collecting and preserving the histories of trans people.

But similar to other archives, trans archives tend to consist mainly of the histories of white middle- and upper-class individuals and organizations.

Although trans research is included today in a number of academic journals, few journals focus on trans experiences. Two notable trans-specific journals are *TSQ: Transgender Studies Quarterly* and the *International Journal of Transgender Health*. *TSQ* is a peer-reviewed journal that publishes interdisciplinary work on the diversity of gender, sex, sexuality, embodiment, and identity. The *International Journal of Transgender Health* (formerly known as the *International Journal of Transgenderism*) is the journal of the World Professional Association for Transgender Health (WPATH) and offers a multidisciplinary approach to the field of trans health.

Trans Studies

Trans Studies represents a significant possibility for trans people, both inside and outside academia. One potent possibility of Trans Studies is the way the field shifts the narrative of mostly cis authors writing about trans lives to trans people creating knowledge, histories, and culture about their own communities. Sandy Stone's 1987 germinal essay "The Empire Strikes Back: A Posttranssexual Manifesto" marked a key turning point in knowledge production about trans lives. More specifically, Stone was one of the first academics to speak from her lived experience as a trans person, rather than non-trans people writing about trans experiences. Prior to Stone's work, trans people shared stories via autobiographies, but these texts were not necessarily included in the academic literature. While there was scholarly interest in trans lives prior to the late 1990s, that interest had a cis gaze; in other words, prior scholarship typically examined trans lives from the perspective of non-trans people. A shift in knowledge production began in the late 1990s as a part of the larger sociocultural movement for greater recognition of trans lives and experiences.

Care for Trans Populations

The growth of medical and psychological interventions for trans people in the United States occurred within the context of academic settings in the 1960s. For those who could access them, these options provided life-saving medical treatment. Innovations in gender-affirming medical care started in other countries many years prior. Although not affiliated with academia, Magnus Hirschfeld began performing medical interventions for trans people as early as the 1920s through his Institute for Sexual Science in Berlin, Germany. Academia—both historically and today—has served as a critical training ground for clinical staff working with trans patients.

Throughout the 1960s, 1970s, and 1980s, many of the leading voices writing about the emergence of what was called *transsexualism* were medical providers, psychologists, and psychiatrists. These clinicians, including such notable scholars as Harry Benjamin, John Money, and Robert Stoller, were overwhelmingly white and male, and much of what they contributed to the academic literature framed trans people in highly medical and pathologizing language.

In addition to his research and writing, Money was principally responsible for the founding of the first gender clinic in the United States, which began at Johns Hopkins University in 1966. Several other academics and academic organizations also helped create gender clinics. Of the university-based clinics that started in the 1960s and 1970s, only a few, including those at the University of Minnesota, the University of California–San Francisco, and the University of Michigan, remain as of 2020. Some university-based gender clinics began significantly later, such as the one at the Oregon Health and Science University, which opened in 2015. Gender clinics represent an important way that academia has bettered the lives of trans people. While these facilities historically engaged in significant gatekeeping and severely limited access to their services, the development of university-based gender clinics enabled thousands of trans people to receive life-giving care.

Research Projects and Centers

Research projects and centers that address LGBTQIA+ issues generally, and trans issues specifically, bolster knowledge production about trans lives. Within the United States, the Social Cognitive Development Lab at the University of Washington conducts research about trans lives within the

broader context of social psychology and related fields. Similarly, the Social Perception, Attitudes, Mental Simulation Lab at San Francisco State University conducts social science research, of which trans projects are a part. Within medicine, the Lesbian, Gay, Bisexual, and Transgender Medical Education Research Group (LGBT MERG) at Stanford University's School of Medicine conducts research about medical curricula. In terms of public policy and the law, Vanderbilt University is home to the interdisciplinary LGBT Policy Lab, and University of California–Los Angeles hosts the Williams Institute.

There are multiple centers concerned with LGBTQIA+ health issues, including the Center for LGBT Health Research at the University of Pittsburgh, the Center for LGBT Health Equity at the University of Southern California, the Australian Research Centre in Sex, Health and Society at La Trobe University, the Lavender Lab at American University, and the IMPACT LGBT Health and Development Program at Northwestern University. Additionally, the University of California–San Francisco and Stanford University began conducting a longitudinal study of LGBTQIA+ health in 2015, which is slated to last 10 years.

As of 2020, there are no LGBTQIA+ research centers across the continents of Asia and Africa, and much of the LGBTQIA+ research conducted within African contexts was completed by U.S., European, or Australian universities. For example, a study of Malawians' attitudes about LGBTQ+ people was conducted by a Malawi doctoral student studying at the University of Bergen in Norway. Outside the United States, it has been more common for nonacademic organizations to conduct research about LGBTQIA+ life, such as the Japan LGBT Research Institute, the Center for Applied Research on Men and Community Health in Vietnam, and the Health Education and Research Association in Macedonia.

There are only a few trans-specific research groups. These include the Trans Research Lab at the University of Wisconsin–Madison, which focuses on mental health research with trans people, and the University of Arizona's Trans Studies Research Cluster, which has its own faculty members in trans studies and produces the journal *TSQ: Transgender Studies Quarterly.*

Trans-Affirming Policies and Practices in Academia

Nondiscrimination Policies

In addition to academia's knowledge production, higher education has played a role in advancing policies and practices that lessen discrimination and increase the livability of trans lives. As a result of academic activism and the advocacy efforts of trans and non-trans people, more than 1,000 colleges and universities in the United States have nondiscrimination policies that include gender identity as of 2020. While these policies can be challenging to enforce and do not necessarily change the culture of an institution overnight, their enactment signals an important shift by recognizing that trans people are subject to discrimination and thus in need of specific policies that address the unique forms of oppression they face.

Coverage of Medical Interventions

According to one estimate, as of February 2020, fewer than 100 U.S. colleges and universities cover gender-affirming surgeries and hormones for trans students under their student health insurance policies, and another couple dozen cover only hormones. More than 50 colleges offer transition-related health care for faculty and staff. These policies represent an important possibility for trans students and staff, but the relatively small number of colleges that provide this coverage indicates the amount of work that still needs to be done. The growing number of colleges and universities that cover gender-affirming medical care is another example of how trans and non-trans activists and advocates have worked together to create change within academia. Knowledge produced within higher education spaces, such as the adverse consequences for trans people of not receiving transition-related treatment, is often used in efforts to change policy and practice.

Gender-Inclusive Housing

In addition to providing trans-supportive medical care, at least 272 U.S. colleges offer gender-inclusive housing as of February 2020. These institutions have created housing units, such as suites, apartments, residence hall floors, or buildings,

where students can have a roommate(s) of any gender. Developing gender-inclusive housing can be difficult in some cases because of the physical architecture of buildings and the lack of gender-inclusive bathroom and shower facilities. But, on some campuses, creating gender-inclusive housing can simply involve designating some residence hall rooms as available to students without regard to gender.

Chosen Name Policies

Another important area of possibility for trans students is the ability to have the names they use for themselves, rather than their dead names (i.e., birth names), appear on campus identification, course rosters, learning management and administrative systems, and campus directory listings. As of 2020, at least 260 colleges enable students to use their chosen names on campus records, but most do not allow a similar change to campus IDs. Increasingly, trans students can indicate their pronouns in course software systems and change their gender markers on campus documents without first needing medical intervention. Taken together, trans-inclusive nondiscrimination policies, transition-related health coverage, and the ability to change their names and gender markers on campus records all improve trans students' academic experiences.

Supportive Spaces

LGBTQ students and staff have successfully advocated for the creation of supportive spaces on campuses, particularly for the establishment of LGBTQ centers. In 2020, there were more than 175 stand-alone LGBTQ campus centers and more than 75 within women's/gender equity or cross-cultural/diversity offices. Most of these centers are housed within Student Affairs, and their primary aim is to serve students' needs through advocacy, social and educational programming, support to individuals and campus groups, and leadership development. These centers contribute enormously to the advancement of trans-affirming policies and practices, catalyzing many of the changes described in this entry.

Trans students have also created supportive spaces for themselves by founding trans student groups and by making LGB student groups trans inclusive. The first LGB student groups to formally include trans people in their names and mission statements and the first trans-specific student groups were formed on college campuses in the late 1990s and early 2000s. Increased trans inclusiveness occurred as a result of greater public visibility of trans people on campuses and efforts by trans activists to change LGB student organizations. However, some of the newly named LGBTQ student groups marginalized their trans members by misgendering them and continuing to focus exclusively on sexuality-related issues. Not until the 2010s did many LGBTQ campus organizations become truly trans inclusive due to the growing number of trans students in these groups and a growing awareness of trans experiences among cis LGB students.

Constraints Within Academia

Knowledge Production

Knowledge production also represents a constraint for trans people within academia. Fields like psychology, medicine, and public health have done significant harm to trans communities. For example, trans people historically and currently report being denied health care, misrepresented in research, and abused by physical and mental health providers. Additionally, trans people are affected by the broader constraints within academe related to knowledge production, including peer-review publication processes and research funding availability. As mentioned earlier, there are few peer-reviewed journals dedicated to knowledge about trans lives, and the most prestigious journals in nearly all fields are unlikely to have any trans or trans-knowledgeable board members. Peer-reviewed academic journals rely on expertise from their respective fields, but there may be few available trans scholars in some fields. This means that scholars producing knowledge about trans experiences often face barriers in the publication process.

In terms of funding, few grants are designed to support trans research. Also, much of the LGBTQIA+ health research in the United States is funded by the National Institutes of Health (NIH). Federal research grants like those from the NIH tend to be awarded to larger public and private research universities and prioritize particular types

of research. Smaller institutions and scholars who are in the humanities or using qualitative or emergent methods are disadvantaged by the current design of the research enterprise within academe.

Curricular Exclusion

In addition to the direct harm done by providers and researchers within higher education, academia is the primary training site for professionals in nearly all fields, including medicine, law, public health, psychology, and social work. Yet, few courses include content about trans lives. In most professional preparation programs, there is little LGBTQIA+ content and rarely opportunities to learn about serving the needs of trans people. In some cases, the LGBTQIA+ content for professional training programs is delivered by faculty in Women's and Gender Studies or related fields. This can pose a challenge for these departments, which are typically small and chronically underfunded, so providing "service" courses forces them to forgo offering courses for students within the major. A further problem with the "service" course model is that the content remains at a fairly introductory level, given how little most non-trans students know about trans people. Thus, despite there being a great deal of knowledge about trans life within academe, scant attention is paid to this knowledge within many fields. The little content about trans people that is included within the curriculum provides insufficient information (and sometimes misinformation) and is disconnected from the lived experiences of the trans people whom these fields should be serving.

Anti-Trans "Feminists"

An additional constraint within academe is that even fields that would seemingly be trans supportive, like Women's and Gender Studies, are not necessarily hospitable spaces for trans people and research in trans studies. A small but well-organized group of trans exclusionary radical feminists (TERFs) within British, Australian, and U.S. academe have made it their mission to undermine trans scholars and write scathing attacks on trans people. Often aligned with conservative groups, TERFs seek to delegitimize trans experiences, especially trans women's credibility. Academia continues to employ TERFs, and academic presses continue to publish their work, despite being clearly discriminatory in their rhetoric and practices.

Lack of Mentorship

A final challenge in knowledge production is the fact that relatively few faculty members have a depth of understanding about trans lives and experiences to enable them to mentor younger generations of scholars. Some institutions do not have any trans-knowledgeable faculty, while others have only a handful in a limited number of departments. The lack of available mentorship constrains the kinds of knowledge that can be produced within academe. Undergraduate and graduate students are often forced to look for mentors and research advisers outside of their fields or even outside of their institutions, which creates obstacles to their work. On the whole, there is great potential for knowledge production within academia, but often it is stalled, fragmented, or limited.

Trans-Negative Policies and Practices in Academia

As much progress as academe has made in terms of creating policies and practices to support trans students, faculty, and staff, too few institutions have taken up the trans-inclusive practices outlined by experts in the field. Academia still has a long way to go to achieve research, scholarship, teaching, and learning communities that provide space for trans liberation and increased life chances. While over 1,000 institutions have added gender identity and expression to their nondiscrimination policies, this represents only about a fourth of U.S. degree-granting colleges and universities, so most trans people in academia still have no recourse if they experience mistreatment. Although nondiscrimination policies have never completely eliminated discriminatory practices, their symbolic function matters. Such policies send a signal that trans people are worthy of respect and inclusion, which can translate to better experiences for trans students, faculty, and staff.

Variable Experiences Within Academe

Trans faculty, staff, and students are subjected to discrimination and harassment within academia in

a variety of ways. For example, trans faculty and staff may experience a hostile work environment because of non-trans students' oppressive behavior. For trans students, non-trans faculty and staff may engage in oppressive behavior that negatively affects their living, learning, and student life environments. Given this variability, efforts to combat anti-trans hostility must similarly take a range of approaches.

But strategies for improving trans people's experiences in academia have been constrained, as the focus has been largely limited to creating policies and practices that address the specific needs of trans students. While such changes are critical to ensuring student success, these efforts must also include staff and faculty. Trans staff and faculty need to have institutional policies and practices in place that can address the discrimination they may experience from students or other employees, and non-trans staff and faculty need to be better trained on trans-inclusive policies and practices to help limit this discrimination.

While a significant amount of education about trans issues and lives occurs within academe, it has not resulted in a fundamental shift in how gender is understood. Changing how non-trans people think about, and therefore engage with, gender as a cultural phenomenon would increase the livability of trans lives and lead to greater liberation for trans people in academe.

Activism

Trans activism refers to purposeful efforts to improve the lives of trans people through making change to law, policy, societal attitudes, living conditions, and other factors that affect equity, justice, and quality of life. Activism necessarily implies an orientation toward changing the status quo and, because of its broad scope, can sometimes include strategies and approaches that conflict with one another. Trans activism has led to legal rights and cultural shifts. Past activism has also modeled behavior, actions, and coalition building that contemporary trans activists use as inspiration and guidance. Activism is important in the trans community to create positive change and as an end unto itself. Trans activism itself is a collection of efforts and works to create positive outcomes for trans people. This entry addresses definitions, types, and histories of trans activism; describes issues in 21st-century trans activism; and discusses important challenges related to the subject.

Defining Trans Activism

Trans activism includes a wide range of activities that involve advocating for the recognition, rights, and life chances of trans people. Generally, activism refers to efforts for social reform. Because it is grounded in social change, activism fundamentally resists the status quo. In the 21st century, the status quo for gender rights is inherently cisnormative and transphobic. Cisnormativity and transphobia are global phenomena, although how these dimensions of oppression manifest around the world vary. Trans activism seeks to disrupt and ultimately dismantle cisnormativity and transphobia in the service of trans rights and life chances.

Among trans communities, it is broadly agreed upon that trans activism is by, for, and about trans people. Some trans activists have picked up a slogan rooted in disability activism: “Nothing about us without us,” which means that efforts related to a minoritized group must include participation by that group. Activism that does not include trans people or is not trans driven is not likely to be considered trans activism, even if its goal is to support trans people. Such efforts might instead be considered trans *allyship*. That said, much trans activism over the past several decades has overlapped with other groups’ interests. For example, some activist efforts in support of trans people are done under the banner of LGBTQIA+ activism, such as AIDS activism and expansion of nondiscrimination policies.

Trans activism includes strategies and efforts small and large, coordinated or independent. Activism may constitute a constellation of planned activities intended to complement each other or individual, even spontaneous, bursts of action. Because of the conflict between global cisnormativity and transphobia, on one hand, and the need to dismantle these ideologies to advance trans rights and life chances, on the other hand, trans activism is necessarily grounded in resistance. Activities that trans activism can entail include but are not limited to protests, demonstrations, letter-writing campaigns, legal actions, marches, riots, boycotts, education, artistic creation, and fundraising. These activities are often done through formal or informal coalitions of individuals and organizations. Many such coalitions, from not-for-profit organizations to less formalized collaborative groups, exist to build capacity for and advance trans activist goals. Other activist efforts are conducted individually. Over the years, some activists have been recognized for their work individually and as part of coalitions.

An important aspect of trans activism is intersectionality. An *intersectional* approach to trans activism considers how multiple systems of domination (e.g., racism, classism, ableism) connect and overlap with transphobia and cisnormativity to create additional harms against trans people who are part of multiple minoritized social groups, especially trans people of color. Many trans activists operate under the banner of intersectional efforts. Because intersectional trans activism focuses on social reforms that address multiple dimensions of oppression, some critics have suggested it is not trans activism because it is not specific only to trans people.

This conflict between intersectional and nonintersectional trans activists characterizes a broader conflict in trans activism. Because of the wide range of what constitutes trans activism, some individual activists and organizations disagree as

to what should be labeled as trans activism. Furthermore, the diversity of people who are trans means that activism by and for one group of trans people may be considered in opposition to another group of trans people. Such conflicts are an important aspect of trans activism in the 21st century.

Some Arenas of Trans Activism

Some of the specific areas in which trans activism has advanced rights and life chances for trans people include but are not limited to law and policy, medicine and health care, education, media, and sports.

Law and Policy

The arena of law and policy constitutes many trans activist efforts, in part because laws and policies implicate many other domains. For example, laws can dictate whether medical practitioners can prescribe gender-affirming treatments and hamper or enable trans people to access educational and recreational facilities. Major areas within the arena of law and policy include decriminalization, antidiscrimination, facilities, and documentation. Decriminalization points to laws that either overtly or subtly criminalize trans lives. For example, anticrossdressing laws criminalize trans existence by requiring people to wear certain amounts of clothing "consistent with" one's assigned sex. Although most trans people are not crossdressers, these laws originated in the 19th and 20th centuries before the contemporary language and culture shifts that have come to recognize the diversity of trans identities. Police would invoke these laws and require trans and other gender-nonconforming people to take off their clothes in efforts to degrade and humiliate. These laws have faded over time through activism in the form of legal challenges regarding individuals' liberty to present more freely.

Efforts to expand antidiscrimination policies within state (i.e., government) and private (e.g., businesses) enterprises represent policy activism to broaden the protection of trans people from discriminatory practices in housing, employment, service, and more. These efforts occur at various levels. Large organizations like the National Center for Transgender Equality conduct such advocacy through a range of legal and educational efforts. Small, even informal groups, such as student organizations, host events and engage with policymakers to broaden existing antidiscrimination policies and/or create new, trans-inclusive policies. Some of these organizations and coalitions also lobby for the expansion of hate crimes laws to include crimes against trans people. Some trans activists, however, have resisted expansion of hate crimes laws because of how such measures serve an inherently oppressive legal system, including what is sometimes called the prison-industrial complex. This tension between working on behalf of trans people within existing systems, oppressive as they are, and refusing to participate in oppressive systems is an example of a difference in activist approaches to intersectionality.

Antidiscrimination policies and the access to and use of facilities are closely linked. For trans people, access to facilities often centers on the availability and use of changing rooms, restrooms, dormitories, and other spaces that are separated by gender. Because many trans people are nonbinary and/or do not fit cisnormative assumptions regarding gender appearance, facilities that are male and female specific leave trans people open to discomfort and even harassment and violence. State and private entities have sought to clarify trans people's use of facilities in inclusive and exclusive ways alike. Trans activists have responded to trans-exclusive facility policies, sometimes called "bathroom bills," through law and policy lobbying; electoral political action; journalism, blogging, and other storytelling to raise awareness; and boycotts of businesses that enforce transphobic, cisnormative facility access.

Documentation refers to personal identification and organizations' recognition of individuals' demographic information, including gender and/or sex. The ability, or inability, for a trans person to change their legal gender on their birth certificate, passport, or other documents is a major example in this arena. Documentation also encompasses how organizations apply gender markers and names to individuals in databases and other information systems. Through activist efforts, such as awareness raising (e.g., trans-inclusive trainings, workplace education) and direct action (e.g., protests, legal actions) to change institutional and state policies, trans people have successfully shifted many organizations' capacity to properly gender and name people in various documents and communications.

How laws are carried out, not just how they are written or intended, affects trans lives. For example, where there are ambiguities in state law regarding sex or gender markers on IDs, individuals within state government can choose to restrict trans people's access to changing their identification. Such restrictions made legally through mundane or everyday decision making are described as "administrative violence." Trans activists, such as Dean Spade, have sought to address administrative violence against trans people by drawing attention to these mundane decisions and seeking redress through new or adjusted policy.

Medicine and Health Care

Medicine and health care policies and practices are highly relevant to trans lives and thus have been an important arena for trans activism. Gender-affirming health care practices include hormone replacement therapy and certain surgeries, including procedures colloquially known as "top surgery" (chest reconstruction) and "bottom surgery" (gender-affirming procedures concerning genitals). These procedures are widely considered essential for many trans people's well-being. Expanding safe, affordable access to gender-affirming medical care and increasing medical practitioners' understanding of gender-affirming practices have been key issues for trans activists. Activism in this area has included trans providers and scholars presenting on relevant topics and providing trainings in their organizations and professional societies, as well as trans community organizations and individuals pushing medical practitioners to adjust practices and policies and lobbying for law and policy changes vis-à-vis health care.

Not all trans people require or even desire medical interventions related to their gender presentation, but all trans people do interact with the institutions of health care and medicine for the range of health care treatments. Efforts to support accessible, affordable, trans-affirming medical care include and transcend gender-affirming procedures specifically. Trans activism thus also aims to expand practitioners' capacity to affirm and care for trans people as patients dealing with the same range of medical conditions that cis people face.

Education

Education encompasses formal education, such as early childhood through postsecondary education, and informal education spaces such as museums and the arts. Trans activism has focused on the inclusion of trans individuals as students and teachers as well as on the content of what is taught. Activism in the education arena overlaps with other areas. For example, access to trans-inclusive facilities is vital for students, who spend large portions of their time in schools, and access to trans-affirming health care is needed for teachers and school administrators. The education area includes its own trans activism as well, from specific contexts like trans-inclusive sex education to the general expansion of concepts of gender in the curriculum and administrative practice. Activism by and on behalf of trans people is a way to ensure the well-being of trans people in schools and to educate other students and teachers by expanding their ideas about gender and the cisnormative binary categories of women and men.

Much activism in education advocates for trans-inclusive curricula. These efforts include teaching about trans history and the contributions to society of trans individuals. Trans inclusion can also manifest through educational activities. For example, a teacher may encourage students to reflect on their identities and the identities of their family and friends in regard to gender or may provide service learning opportunities with trans advocacy organizations. Trans activists urge these curricular efforts through school boards, laws regarding education, and direct contact with teachers and educational administrators.

Sex education is a major focus of activist attention. Trans-inclusive sex education rejects binary categories of sex, sheds cisnormative expectations regarding how individuals' bodies develop through puberty, and includes information about managing transition, such as healthy use of binders and puberty inhibitors. Providing trans-inclusive sex education is broadly seen as a trans activist effort and is carried out by organizations like Planned Parenthood. Additionally, in some regions and municipalities, trans-inclusive sex education is integrated into school curricula. For example, Ontario, Canada, briefly required trans-inclusive sex education in the 2010s before

right-wing politicians and trans-exclusive feminist groups reversed that policy.

Beyond curricular change, trans activists and educators seek to dismantle the gender binary and other cisnormative assumptions in schooling. For example, trans scholars, educators, and activists have challenged the use of binary gender reporting in the teaching of statistics. Through emergent scholarship in the late 20th and early 21st centuries, trans scholar-activists have advanced knowledge on how to support trans students from kindergarten through higher education. Furthermore, many activists create and share stories, fictional and nonfictional, about trans people and communities with schools and educators to promote the broader inclusion of trans perspectives and lives in education.

In higher education settings, trans students participate in activism through a variety of means, such as LGBTQIA+ organizations, meetings with institutional leaders, and campus committees. These activist efforts provide opportunities for trans college students to learn about organizing and strive to make their institutions more affirming.

Media

The effort to create and share stories about trans people transcends education. Many trans people have created film, television, music, journalism, books, art, and other media that tell trans stories. In media, trans activism largely constitutes a push for diverse representations that reject stereotyping and other harmful portrayals of trans people. Although trans representations existed in media prior to 2000, widespread efforts to spotlight trans stories, hire trans talent for these stories, and challenge cis people's (mis)representations of trans lives largely emerged in the 21st century. Notably, in the 2010s, Laverne Cox became the first openly trans person in the United States nominated for an Emmy Award in an acting category (for her role in the television show *Orange Is the New Black*); Janet Mock, trans media creator and activist, released her bestselling memoir, *Redefining Realness;* and a number of trans-related television shows and films premiered, including the television show *Pose,* which had the most trans writers, producers, and actors of any program, and the film *Tangerine,* whose main characters are trans sex workers played by trans actresses Kitana Kiki Rodriguez and Mya Taylor.

Trans activism through media is characterized by artists and activists engaging in storytelling, awareness raising, and advocating via various media platforms for trans rights and life chances. For example, Laverne Cox used her celebrity status to raise awareness of the story of CeCe McDonald, a Black trans activist who was imprisoned for defending herself against and killing a transphobic, racist attacker.

Sports

Trans activism in sports relates primarily to the ubiquitous binary gender categorizing of athletic competition. That is, because the vast majority of amateur and professional sports contests are sex segregated, with sex determined by cisnormative rules, trans participants are all but excluded. Even the Gay Games has discriminated against trans athletes. But despite these instances of exclusion, many trans athletes still train and compete locally and/or through organizations that practice trans inclusion. Such participation in the face of attempts to sideline trans people in sport is an activist effort, as are efforts to raise awareness about trans athletes and gender diversity more generally and to change the policies of sport governing bodies to enable trans people to compete.

Examples of Trans Activism in History

Scientific Advancement

In some contexts, scientific research can constitute activism. The early 20th century saw major strides regarding the science of gender diversity that challenged Western notions of the gender binary. Pivotal to these discoveries was the Institut für Sexualwissenschaft, or Institute for Sexology, founded by Magnus Hirschfeld in Berlin, Germany, in 1919. Although Hirschfeld was not trans, the Institute employed trans people and performed some of the gender-affirming medical interventions that trans people sought. In the 1930s, Adolf Hitler denounced Hirschfeld, and Nazis destroyed the Institute. Some of the Institute's work continued, both through the training of doctors who would later advance trans-affirming medicine and through case descriptions of trans people, some of which were included in Hirschfeld's 1910 book *The Transvestites*. Scientists and physicians thus

engaged in activism on behalf of human rights and dignity.

Social Networks

In the mid-20th century, informal and formal social networks of trans people in the United States emerged, creating a foundation for collective action. In the 1940s, Louise Lawrence, who would, in the 21st century, be recognized as a trans woman, developed correspondence networks with people who were arrested for crossdressing and housed people seeking trans medical care in San Francisco. Virginia Prince, a self-described transvestite who was part of Lawrence's social network, went on to build an even broader network in the 1950s. In 1952, Prince and other transvestites published *Transvestia: The Journal of the American Society for Equality in Dress,* a newsletter that would be the first of many political, awareness- and solidarity-focused publications produced by, about, and for trans people. Newsletters and zines would continue to be major sources of sharing trans art, poetry, stories, and news for decades to come. In the 1960s, Prince founded the Foundation for Personal Expression, which later transformed into the Society for the Second Self, or Tri-Ess. These organizations formalized the social networks Prince and other transvestites had created. In the wider social context of McCarthyism in the United States and violence against queer people, forming these networks constituted radical activism and, in fact, risked legal consequences to the activists.

The late 19th and 20th centuries also witnessed the emergence of drag ball culture. Ball culture involved young people dressing up and was especially prominent within Black queer communities. Throughout the 20th century, ball culture provided social spaces in which people could play with gender and develop social networks connected by gender nonconformity. Resistance and activism might be expressed in these contexts through dress and dance, but it was no less political in nature than the street protests that symbolized trans activism in the 1960s.

Riots, Protests, and Demonstrations

Spontaneous and planned responses to police violence represented some of the most visible moments of trans activism in the mid-20th century in the United States. The Stonewall Riots in particular are famous for their role in trans history and LGBTQ+ history more broadly. Prior to Stonewall, however, there were protests against police at Cooper Do-nuts in Los Angeles in 1959, Dewey's in Philadelphia in 1965, and Compton's Cafeteria in San Francisco in 1966. In the cases of Cooper's and Compton's, police harassed patrons, many of whom were street queens, sex workers, and/or gay men, until the patrons fought back. Following the riot at Compton's Cafeteria, participants in the resistance and other allied individuals returned a second night and, in time, incited further organizing through organizations such as the youth organization Vanguard and the peer support group National Transsexual Counseling Unit. At Dewey's, the management began refusing to serve gender-nonconforming youth, until customers staged sit-ins and picketed outside the restaurant.

Likewise, Stonewall marked an important historical moment for trans activism, as well as the beginning of further organizing. In the early morning of June 28, 1969, police raided the Stonewall Inn in New York City's Greenwich Village, and the bar patrons who were allowed to leave remained outside, eventually resisting and fighting back against police. Many trans people were involved in the riots, including notable trans activists Stormé DeLarverie, Marsha P. Johnson, and Sylvia Rivera. It is believed that DeLarverie, Johnson, or another drag queen or crossdresser (as many trans people were described at that time) was the first to fight back against the police at Stonewall. After hours of fighting with police in the morning of June 28, groups of trans people, street youth, gay men, and others who had frequented Stonewall and other area gay bars returned to the site the next night to protest and continued to do so in the nights that followed.

Protests continued as visible activism efforts in subsequent decades, through movements such as antiapartheid, AIDS activism, Arab Spring, Occupy Wall Street, and Black Lives Matter. Although none of these were specific only to trans people, trans activists rallied to many of these and other contemporary causes to address multifaceted issues such as anti-Black police violence and wealth inequities.

Organizing

In some ways, trans organizing dates back to Hirschfeld's Institute for Sexology, but it increased exponentially in the 1960s, especially after the riots at Compton's and Stonewall. Conversion Our Goal (COG), for example, was founded in San Francisco in 1967 and served as a support group, connecting trans people to resources and to each other. In New York City, among the organizations created in the months after Stonewall was STAR (Street Transvestite Action Revolutionaries), founded by Johnson and Rivera. Through STAR, Johnson and Rivera aimed to safely house and care for homeless trans youth and to resist and protest police violence. STAR lasted from 1970 to 1973, but Johnson and Rivera continued agitating for trans youth and drag queens within the gay liberation movement for the rest of their lives.

The Gay Liberation Front (GLF) was one of the best-known organizations to emerge after Stonewall. New York City GLF activists planned the Christopher Street Liberation Day March in 1970 to commemorate Stonewall, and several U.S. cities followed suit. These first-anniversary recognitions of the riots in time spread worldwide and spawned organizations that celebrate June as Pride Month. Although trans people were integral to resistance at Stonewall and part of what was described as the gay liberation movement, they were purposefully sidelined within GLF and other gay organizing of the time. Trans organizations like STAR and the Queens Liberation Front (QLF) took the mantle of centering trans people in their efforts.

The sidelining and exclusion of trans people in gay and lesbian groups, as well as in feminist organizing, continued for the rest of the 20th century and, to a lesser degree, into the early 21st century. Trans organizing in this time period involved both creating trans organizations and agitating for inclusion in gay and lesbian and other organizations. In the 1990s, 2000s, and 2010s, many gay organizations changed their names and sometimes missions to be more trans inclusive, although transphobia persisted in some of the organizations that had appended a "T" to their use of "LGB."

Trans people continued to build organizations in the service of trans rights and resistance. Trans activism grew exponentially in the 1990s with the creation of a wide range of organizations, including the American Educational Gender Information Service (AEGIS), founded by Dallas Denny, and Transexual Menace and, later, the Gender Public Advocacy Coalition (GenderPAC), founded by Riki Wilchins. Through AEGIS, Denny circulated information about trans issues and hosted large conferences and gatherings. Transexual Menace was a protest group, and GenderPAC lobbied for trans rights laws and policies.

Vigils and Remembrances

Transexual Menace, a direct action group founded in New York City in 1994, was involved in protesting and holding vigils for trans people killed because of their gender identity/expression. One such victim was Brandon Teena, a white transmasculine person who was murdered by transphobic assailants in 1993. The 1998 murder of Rita Hester, a Black trans woman, spurred Gwen Smith to create a website to honor trans victims of violence; the website later evolved into the Transgender Day of Remembrance, a day that memorializes those killed in anti-trans hate crimes and calls for trans activism internationally.

Storytelling

In the early 1990s, trans author and activist Leslie Feinberg published two works that proved foundational for trans life in the years to come: hir memoir-style novel, *Stone Butch Blues,* and the political manifesto, *Transgender Liberation: A Movement Whose Time Has Come.* Queer studies, which offered intellectual bases for trans existence, emerged around this time in academic circles and set the foundation for scholarship and the later emergence of trans studies as an academic field. In and outside of the academy, trans stories were increasingly told by trans people, in contrast to much of the 20th century, when trans lives were described in medical, pathological, or legal terms by non-trans people.

The emergence of massive online social networks such as Tumblr, Twitter, Instagram, and Facebook in the 2000s and 2010s enabled individuals and groups to use online platforms to tell stories, advocate, and connect. On these platforms, hashtags (i.e., keywords that follow the # symbol) enabled connections between posts. Site

users employed hashtags such as #TransIsBeautiful and #GirlsLikeUs to advance positive, affirming images of trans people. Social media also presented a new forum to challenge people, including elected officials and celebrities, who promoted cisnormativity and transphobia. Finally, trans people have used social media websites to build social networks, which enables greater connectivity among trans people and more opportunities for activism in the community.

Benefits of Trans Activism

The goals of trans activism are to expand rights for and improve the lives of trans people. These goals benefit trans people's capacity to live and thrive. Furthermore, the expansion of rights for trans people benefits cis people. For example, some people who experience harassment because of their gender expression are cis; that is, although the person is not trans, they may be mistaken as trans by a transphobic aggressor. Using harassment and violence to enforce cisnormativity can extend beyond trans people to anyone who expresses gender outside traditional binary norms of femininity and masculinity. Manifestations of transphobia and cisnormativity can thus harm cis people, so eradicating anti-trans oppression is also in their interest.

Research finds that trans people who participate in activism experience positive psychological and social benefits. Coalitions of trans activists create a sense of community for those involved that may not have been fostered otherwise. Historically, those coalitions enabled trans people to create social networks that began through arrests and other acts of police violence and private business exclusion, such as the protests at Cooper Do-nuts and Stonewall. Such community, and the positive goals for trans people they work toward through activism, can support trans people's social connections and positive sense of self. The emergence of digital forms of activism, including social media campaigns and virtual community organizing, enables 21st-century trans activists to mobilize more quickly and on a larger scale than was possible when trans activist movements began. Even with the affordances of technology, however, contemporary trans activism relies on its heritage of courage and resistance in the face of a cisnormative and transphobic status quo.

Responding to this status quo creates an inherent paradox in trans activism: Participating in activism can benefit trans people, yet it requires emotional, relational, and physical energy as well as time focused on transphobia and cisnormativity, rather than simply living one's life in a state of equality and justice. Encouraging trans people to involve themselves in activism for the benefits therein ignores that such activism is a response to the harms of cisnormativity and transphobia. Although trans activism is beneficial, ultimately dismantling aspects of society that necessitate activism would be more beneficial.

Conflicts in 21st-Century Trans Activism

Trans activists in the 21st century are presented with some conflicts that play out across arenas and types of trans activism. Generally speaking, conflicts are rooted in representation and the diversity of identities and priorities within trans activism, as well as in the overlap (or lack thereof) with other groups and issues.

A challenge that arises in activism is that trans people who hold majoritized identities (e.g., white, wealthy) often dominate discourses and priorities related to trans activism, to the detriment of others in the community. This dynamic can lead to the erasure of trans people of color, especially Black trans people, and other trans people with multiple minoritized identities. Such erasure can include ignoring those communities' priorities and marginalizing the people themselves within activist efforts.

The differences between goals can emerge in a variety of ways. One example is related to inclusion in the military. Some U.S. trans activists advocated to lift the ban on trans servicemembers in the Armed Forces. Other trans activists opposed this effort, arguing that allowing the military to become trans inclusive would strengthen what is called the military–industrial complex and concomitant harms against minoritized people globally. This difference exemplifies conflicts between trans activists who seek inclusion in all spheres of life and trans activists who embrace an intersectional approach to fight against all forms of oppression.

Efforts to challenge the military–industrial complex point to trans activism that overlaps with

other groups' activism. Likewise, many trans activists partner with non-trans people in the service of issues such as immigration, policing, and environmental justice. For example, many trans people supported actions by Black and Latinx organizations in the United States to protest against police violence, incarceration, and immigrant detention, noting that Black and Latinx trans people experience considerable harm through the criminal justice and immigration systems.

Adoption and Foster Care

The majority of trans people describe adoption or foster care as their preferred way of becoming a parent—however, little is known about the actual number of current trans adoptive and foster parents (in comparison to lesbian and gay adoptive and foster parents: for example, in 2007, it was estimated that lesbian and gay parents are raising 4% of adoptive and 3% of foster children). While adoption and foster care are the ideal pathways to parenthood among trans people, there are a number of financial, legal, and logistic barriers that they must navigate. Trans people represent a significant pool of potential parents for a large population of children in need, along with possessing unique strengths as prospective adoptive/foster parents.

According to the U.S. Department of Health and Human Services, in 2017 there were over 400,000 children in the foster care system, 60,000 of whom were legally adopted, with 70,000 remaining available for adoption that year. Each year in the United States, the majority of children who are adopted are done so through the foster care system, with about a quarter of adoptions occurring internationally and a tenth being adopted domestically (outside of the foster care system). Based on a combination of representative U.S. surveys in 2007, over 2 million LGB people want to become parents through adoption or foster care and 111,000 LGB parents are currently raising adopted children, with thousands more parenting children from the foster care system. Some experts have emphasized that these numbers are great underestimates. Although the current number of trans adoptive and foster parents is unknown, the majority of trans people describe adoption and foster care as their ideal method of becoming a parent.

Among childfree trans people, adoption and foster care is described as the ideal pathway to parenthood, and this trend is on the rise. The majority of trans youth see adoption or foster care as how they envision becoming parents, with many not even considering biological parenthood. For some, adoption may not be their first choice, but is it the most realistic and feasible option due to the availability and functionality of their or their partner's reproductive systems (i.e., they understand that hormonal therapies would need to be delayed

or stopped due to the negative impact on sperm production and ceasing of the ovulation cycle). Many trans people describe their main motivation for wanting to become adoptive or foster parents as a way to give back to children in need and contribute to wider society.

There are a number of ways that trans people can become adoptive or foster parents, each with its own unique strengths and barriers. Trans people can become adoptive or foster parents as a single individual or in the context of a couple. The adoption process can take different forms, depending on the type of adoption agency. Typically, potential parents can work with either of two different types of agencies, public or private. Public agencies typically work within local or state child welfare systems. With public agencies, birth parents have lost their legal rights to their children, which often results in a lack of involvement of the birth family in the placement process. In addition, public agencies are more likely to have children who have higher rates of special needs or trauma-related challenges and are typically older. In contrast, private agencies facilitate both domestic and international adoptions. These agencies typically involve the birth family in the adoption process, often making decisions regarding potential adoptive parents. Last, private adoption is typically more expensive than public adoption.

Unlike adoption, foster care is not a permanent placement and does not always include the opportunity of future adoption. With foster care, agencies prefer to place children with biological relatives or family members first before allowing for permanent placement or adoption. Currently, over 400,000 children are in the U.S. foster care system, with about a quarter available for adoption. Owing to an insufficient number of qualified foster parents compared to the number of children, a quarter of these children will turn 18 years of age before having a permanent placement. It is important to note that children in the foster care system tend to be considered "higher risk," since they are more likely to be older, have a history of childhood trauma and abuse, have higher rates of mental and physical health difficulties, and more often require more specialized care and services. Last, it is important to note that foster care is less of a financial burden compared with adoption, which can make this pathway to parenthood more feasible.

Barriers to Adoption or Foster Care

Even with the availability of adoption and foster care, trans people face a number of barriers to becoming parents through these methods. In general, society has negative views about trans people as parents, typically based on heterosexist and cissexist beliefs that children need both a mother and father who are cisgender. In one study, participants reviewed descriptions of potential adoptive parents, with the only differences being the parent's sexual orientation or gender identity. In general, heterosexual cisgender parents were rated ideal, with the trans parents being the least preferred, especially among those who held more negative views toward trans people. These negatively held views of trans parents are reflected in many laws and policies regarding adoption and foster care.

A number of legal and policy level barriers affect potential trans parents. Currently in the United States, there are no federal legal protections for gender-based discrimination toward trans people. Being trans is not in itself a reason for agencies to deny services or refuse to work with potential parents, but owing to a lack of federal legal protection, agencies can make these decisions based on personal beliefs or opinions. As of 2020, 11 states allow state-licensed adoption and child welfare agencies to deny placements or refuse to work with trans people based on their gender identity. Only 24 states, along with Washington, D.C., prohibit discrimination toward potential parents based on gender identity. Among the remaining 26 states, 4 have protections regarding sexual orientation but not gender identity, and 22 states have no explicit legal protections based on gender identity or sexual orientation. Many agencies are willing to work with trans potential parents, but many trans people understandably (i.e., based on their experiences with discrimination in the broader society) believe that discrimination is pervasive and worry that they will face discrimination in the adoption process.

For those who decide to begin the process of becoming an adoptive or foster parent, they first need to find an agency willing to work with them. Even if an agency is willing to work with trans people, there remains the fear that other individuals within these agencies, the family court system, or birth families will discriminate based on gender identity. Because of these fears, trans people may

decide to conceal their gender identity—although there are legal and practical implications of this nondisclosure.

Legal professionals generally see early disclosure as important to facilitate the adoption or foster care process. The process, which involves stringent background checks, including medical and mental health histories, could result in the discovery of a person's gender identity. Many agencies require disclosure of all personal information at the beginning of the adoption or foster care process, which would include gender identity. If not disclosed prior to signing a contract with an agency but discovered later, that could be a violation resulting in termination. In contrast, some legal scholars have discussed that requiring disclosure could be an invasion of a person's privacy. Some couples have found additional ways to navigate nondisclosure, such as in a situation where one partner is trans and the other is cisgender. In this situation, the cisgender person could go through the adoption or foster care process as a single parent, without disclosing the presence of a partner. This would result in the trans parent not being legally recognized as a parent or guardian to the child. In sum, fears regarding disclosure, experiences of discrimination, and lack of legal protections can result in potential trans parents being apprehensive or deciding not to pursue parenthood through adoption or foster care.

Unique Strengths of Trans Adoptive or Foster Parents

Although trans people have reported perceiving and experiencing barriers in attempting to become parents through adoption or foster care, there are a number of potential strengths that trans people bring to being adoptive or foster parents. For example, trans people are more willing to adopt or foster children who are older and have behavioral difficulties, physical disabilities, and mental health diagnoses, compared with their heterosexual cisgender and sexual minority peers. In addition, trans people are comparatively more open to adopting or fostering sibling groups, which would allow more children to remain with members of their birth families.

There are two additional groups—namely, children of color and LGBTQ children—for whom trans people could provide unique personal support. Due to trans people's being aware of, and often having had, negative experiences associated with these identities, trans people are in the unique position to relate to and understand these youth. Therefore, trans adoptive parents can provide valuable insight into these children's personal needs, along with being able to provide personal validation of these children's experiences. This is important given that, in the U.S. child welfare system, racial and ethnic minority children are disproportionately represented, specifically non-Hispanic Black children. According to the Adoption and Foster Care Analysis and Reporting System, in 2017 these children made up 23% of all children currently in the foster care system, although they comprise only 14% of the general population. Interestingly, trans people are more open to adopting or fostering a child of color, along with being more likely to identify as nonwhite, compared to their cisgender peers. Currently in the United States, over half of the adopted racial and ethnic minority children in the child welfare system have been adopted by white identified parents. Although controversial, some discuss potential issues with transracial adoption—specifically, whether white parents are the best adoptive parents of racial and ethnic minority children. Since one quarter of the children in the child welfare system identify as nonwhite, trans people represent a potential parent population with similar racial and ethnic demographics. Another statistically high population in the child welfare system are LGBTQ youth. In a study published in 2019, 30.4% of the youth in the foster care system identified as LGBTQ, along with 5% identifying as trans. Compared with the general population, LGBTQ youth are three times more likely (11.2% of general population) and trans youth are five times more likely (1.2% of the general population) to be in the child welfare system.

Conclusion

For trans people, becoming a parent through adoption or foster care is often seen as the preferred way to become a parent. With thousands of children in need of loving homes and thousands of potential trans people interested in becoming parents this way, trans people are a deeply undervalued

population in regard to the child welfare system. Negative assumptions or myths regarding trans people's capabilities as parents, along with the institutional discrimination trans people may face from adoption agencies, the child welfare system, and the legal system, cause millions of potential parents to be denied their right to become parents. With a strong commitment to becoming parents through adoption and foster care and the potential to fill multiple gaps within the child welfare system, trans people are an extremely underused resource available to the child welfare system and thousands of children in need.

Affirmative Therapy

For many years, therapists have often been perceived by trans people as gatekeepers to transition. Doctors would not write a hormone prescription without a referral letter from a mental health specialist; surgeons would not perform transition-related surgeries without a similar referral letter. Viewed in this light, many trans people did not consider that therapy might be beneficial beyond providing referral letters. This entry addresses what affirmative therapy might look like, beyond providing letters leading to treatment with hormones and surgery.

There are few populations as diverse as trans people. (Trans people cannot even agree on terminology, as some will not use the umbrella term *trans*.) The only thing this population has in common is calling into question birth gender assignment. What does affirmative therapy look like, then, for a population this diverse? Are there any commonalities in the therapeutic process from one client to the next? Absolutely.

Beyond the diversity of the population, another consideration is the complexity of the transition process. Few processes rock the lifeboat as thoroughly as transition. The changes that an individual undergoes may be dramatic externally, with the client looking completely different some years into transition. The changes may be completely internal and just as dramatically deep for the trans client whose path does not include physical transition. Yet again, there are indeed commonalities in the therapeutic process across diverse trans clients.

A point of reassurance: Nothing stays the same, everything changes, and none of the decisions belong to the therapist. The job of the therapist is not to diagnosis identity or to proclaim, "This is who you are." Imagine lining up a group of people and going down the line proclaiming certain people are gay or lesbian while others are not. Although that may sound ludicrous, the presence of the diagnostic category Gender Dysphoria in the American Psychiatric Association's fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-5*) implies the notion that therapists can diagnose a trans person's identity.

The diagnosis of identity belongs to the client. The job of the therapist is to facilitate the process

and to provide clients a safe space to conduct the necessary exploration from which to make an informed decision about who they are. Deep self-exploration, going back to their earliest childhood memories of gender emergence, requires trust and centeredness. The job of the therapist, then, is to create the safe holding space for the client to access, the space that allows them to bring painful, upsetting, or overwhelming memories and current experiences into the moment.

The Therapeutic Setting

People whose identities are marginalized become vigilant in assessing the safety of their surroundings. Here are things a trans client might look for (either consciously or not) in assessing a therapist's office for emotional safety.

First, the building infrastructure itself. On their initial visit to a therapist's office, it is likely the trans client will notice the bathroom signage down the hall. How gendered is it? The caution that new clients always feel may be heightened for the trans person by bathrooms labeled "Men" and "Women" with no indication of awareness of trans or nonbinary identities.

Second, the waiting area. How neutral is the color scheme regarding gender? If there are magazines, what titles are they? Anything LGBTQ is a good sign, especially if it is current. However, having one copy of a 3-year-old magazine sends entirely the wrong message, one of tokenism. Are there any posters or artwork that show support for all kinds of identities?

Third, the therapy office. Is the therapist sitting in a position of equality with the client? Similar chairs? Is the therapist behind a desk? Again, clients who are marginalized have a heightened awareness of power differentials.

Fourth, the intake paperwork. Reassuring to a trans client, for example, is paperwork that states: What pronoun would you prefer I use for you in my chart notes? Even more reassuring is not asking about gender on initial paperwork at all, as this allows for a matter-of-fact conversation with all clients during the first session. This lets trans clients know that the therapist is not on autopilot about gender.

The therapist can then discuss how various insurance companies handle gender, that there may be a need to misgender a nonbinary client because of the constraints of the billing system, and that the therapist recognizes pronouns and names may change over time and the client should let the therapist know if their pronouns shift, or they would like to try out a new name for a time, or that they have chosen a new name. The conversation itself is an intervention, normalizing that the therapist is aware that birth-assigned gender is not fixed reality.

The therapeutic alliance is the most important factor in working with any client. All the trans-supportive infrastructure in the world is not going to create that spark of connection that leads to excellent work.

The Therapist's Personal Gender Exploration

This raises the important issue of the actual therapist. How much internal work has the therapist done in assessing their own gender? "Informed about who they are" requires the client to do deep soul-searching into the nature of gender, gender roles, gender expression, how they feel about the gender they were assigned at birth, and whether there are aspects that work for them while others do not.

The question underlying all this exploration is, "What form of transition away from my birth gender assignment is right for me?" The therapist who has done similar self-exploration will be of greatest benefit to trans clients. If the therapist identifies as cisgender, is this identity based on self-exploration or an automatic assumption?

In many cultures, gender is viewed as fixed reality, automatically matching certain genital configurations. Gender is assumed at birth from a cursory examination of the baby's physicality. Often these days, this pronouncement is made before birth, based on an ultrasound examination. The baby is gendered before seeing the light of day and sometimes is feted with a gender reveal party while still inside the womb.

Some parents are now making the logical connection: Since there are trans people having to transition, this means the gender assigned them at birth was inaccurate. How, then, can one accurately assign gender at birth? Such parents have brought gender into consciousness as a social process, not a

fixed reality that automatically correlates with genitalia. It is precisely this paradigm shift about the nature of gender that is required of the therapist who works with trans clients. Here are some exercises that can help facilitate this paradigm shift:

- If the therapist has access to a multistall public bathroom that is open to men and women alike, experiment with using it and note the resulting emotions.
- If the therapist lives in an area where it is legal to use whichever bathroom fits their identity, regardless of their physicality or mode of dress, experiment with using the "wrong" bathroom and note what emotions arise.
- A cisgender, male-identified therapist might dress as a woman and move through the world in various social situations, doing their best to be seen as a woman, not as a man in a dress. Note the difference in social interactions and boundaries, as well as the resultant emotions.
- If the therapist cannot be seen as a woman, they will be seen as a man in a dress. Note the resultant social interactions and emotional responses.
- A cisgender female-identified therapist might attempt to be seen as an adult man. (This may require not speaking in public.) If the therapist has experience with theatrical makeup or know someone who does, adding facial hair will augment this experiment. Note the resultant social interactions and emotional responses.

These experiments are designed to highlight the nature of gender as a social process. Social boundaries, particularly with strangers, derive in part from unconscious assessments of gender. Bringing the system into consciousness as just that, a system, will help the therapist understand a trans client's challenges.

These exercises can only give a glimpse, as the cisgender therapist is not changing their hormone balance. Shifting from being estrogen based to testosterone based or vice versa changes one's perspective completely. People do not want to believe they are little more than a series of chemical reactions; those who have transitioned with the introduction of hormones understand how profoundly hormone balances affect the filter through which humans experience the world emotionally and intellectually.

Cisgender women who have been pregnant, have gone through menopause, or had erratic periods have experienced changes in their hormone balance, allowing a glimpse of what it feels like if the balance changes significantly. Cisgender men who have taken testosterone to boost low levels may remember experiencing an increase in energy and mental alertness, as well as a heightened sense of centeredness.

Testosterone and estrogen are naturally occurring hormones present in all humans. Those who transition physically are changing the dominant hormone in their body. Aspects of this process may resonate with the cisgender therapist, allowing a point of identification with a trans client's process as they shift hormone balances.

Whatever modality resonates with a particular therapist, their job is to help a client reframe past experiences in service of defining the future. There are few cultures that welcome and celebrate trans identity; most trans clients have been raised within a culture that denigrates, mocks, or denies their identity. Helping them redefine gender as an innate identity issue, one only they can address, will help them develop the self-esteem and centeredness required to make the best decisions about transition.

Whether physically transitioning or not, whether nonbinary or claiming "he" or "she" as a pronoun, all trans clients will find their path smoother if they own their identities as being just fine. A therapist who models a matter-of-fact attitude of identity exploration as a good thing, regardless of where the journey takes the client, is giving the client precisely what they need from their early transition therapist.

The Therapeutic Alliance

One paradox of transition is that the closer the relationship between a trans client and a friend or family member, the less likely it is they can turn to that person for unconditional and congratulatory support during early transition. Initially, the friend or family member is going through their own transition process. The friend or family member has to let go of the old before they can be expected to embrace the new identity. This entails some form of loss and grief process—not a time for providing congratulatory support.

The close intimacy of the therapeutic alliance may provide the trans client with the one person who will congratulate them unreservedly when they reach each milestone—the legal name change, the ID card or driver license with the right gender, coming out at work or school, the first date—whatever the milestone is, the therapist experiences no grief in facing it with them. Therapy affirms the journey, wherever it leads.

Transition is an overwhelming journey for any client to consider. An analogy useful to share with trans clients is this. Transition is like driving down a dark deserted road at night. The headlights only illuminate the next 50 feet. Others have traveled this road, yet the client is alone on the journey. They can travel 1,000 miles down that road only ever seeing the next 50 feet. What a leap of faith to undertake the journey—and what a gift to a therapist, to be a companion along the way toward blossoming.

Agender People

Agender is a gender identity term that can be defined as "without gender." Conceptualized outside the gender binary, agender is most often included under the category of nonbinary gender identities, which, in turn, exists under the larger trans umbrella. Agender is most similar in meaning and use to other gender identity terms that signal an absence of gender, such as genderless, gender neutral, and neutrois. Current understandings of agender people have arisen from both the scientific literature and community-based forums, which provide more nuance than current research can offer.

Scientific Literature

The scientific literature rarely speaks about agender people as a distinct group. Rather, it highlights their experiences alongside genderqueer, genderfluid, and gender-nonconforming individuals and as part of the larger nonbinary umbrella. Research focused on nonbinary identities has worked to distinguish the unique experiences of nonbinary people from those of binary trans people (e.g., trans men, trans women), who are more consistently studied. The literature on nonbinary identities largely aims to understand a marginalized experience (nonbinary) within a marginalized experience (trans). Thus, scholars study how agender and other nonbinary people conceptualize their identities outside the binary. Research also speaks to how agender people negotiate their identities socially, noting that the disclosure of an agender identity is likely met with questions, bias, and microaggressions. Often the underlying assumptions behind these reactions serve to question whether agender is a legitimate identity, suggest that agender people are not "sufficiently" trans, or otherwise force agender individuals to have to defend the legitimacy of their experience.

Qualitative, identity-based research focuses on how agender people make meaning of their gender. For example, agender people often describe having no internal gender or state that their gender is nonexistent. Many also explain that they are not attached to gender, that gender is not salient to their understanding of self, or that their identity is not modified by gender. In addition to characterizing their gender using these more traditional agender explanations, agender people in a recent study also described their gender using five other types of terminology: binary, nonbinary, blended, fluid, and transgender. Although sometimes participants did use binary language (female/male or feminine/masculine) to describe their gender identity, they did so to convey the ways that these terms, even combined, did not quite capture their identity. Similarly, some participants explicitly used nonbinary terminology to convey that their identity did not reside anywhere on a continuum between female and male. Participants also described their gender identity using blended terms, where gender was described as being "both" female and male, or as a blend or mix of the two, and fluid terms where the central characterization of their gender identity rested in flexibility and change (across time and context). Finally, agender participants used transgender terms (e.g., FTM, trans, transmasculine) as a way to describe their identity.

Research shows that many trans individuals use multiple labels for their gender, and this is true for agender people as well. Agender people may exclusively use the term *agender* to describe themselves, or they may simultaneously use multiple labels (e.g., agender, nonbinary, trans). Often individuals will shift usage of labels strategically in order to negotiate across different social situations. The approach to studying agender people reflects this complexity. While agender people are most often included in research studies and grouped with people of other nonbinary identities, they may also be included in studies of trans individuals, where people of all non-cis identities are grouped together.

Demographically, the research on agender people has suggested that nonbinary individuals (inclusive of agender people) tend to be younger than other individuals in the trans community. However, it is important to note that the majority of the research that includes the experiences of agender people has been conducted online, often recruiting participants from social media outlets, such as Reddit, Tumblr, and Facebook, that provide support and community for agender individuals. It is not surprising, then, that the most nuanced and up-to-date understanding of agender people can be gleaned from community and online resources.

Community Literature

Agender people use social media sites in a variety of ways: to build community, gather and share information, vent about microaggressions, and as a tool for visibility and identity affirmation. In their personal accounts, agender users convey the difficulty of coming out and being recognized as an agender person when there are so few cultural markers to make their identity intelligible to others. Agender people are heterogeneous in their gender presentation and pronoun use. However, many people internalize universal norms that equate agender with androgyny or body dysphoria, leading users to ask questions like, "Do I look agender?" or "Am I trans enough?" In the absence of formal organizations or in-person community resources, online communities provide invaluable educational resources.

On one hand, there is a great need to bridge scientific and community literatures and for the scientific literature to account for the diversity of agender populations. On the other hand, studying agender as its own identity category may not be the best methodological or theoretical solution either. Because agender people may use multiple labels (and because many others do not have access to this term), comparing agender people with other nonbinary identities may not produce clear results. As more identity categories proliferate and shift how people articulate and experience gender, researchers must find ways to capture agender people's experiences without relying on identity categories that may or may not account for the totality of trans lives.

Aging

Aging is typically understood to mean the changes that occur, over time, in a living organism—or the degradation of function that accompanies the passage of clock time. The fields that study aging are divided into two general areas: geriatrics (the medical/psychological facets of aging) and gerontology. The field of gerontology is divided into three subareas: *biomedical aging* (the study of biological age-related changes in the body), *psychosocial aging* (the study of age-related psychological and social changes over time), and *health planning and social policy* (the study of aging as it relates to such areas as Medicare/Medicaid, Social Security, end-of-life challenges, and health care disparities and access).

Trans people face many of the same aging-related challenges as other individuals. However, they also have many unique ways of experiencing the consequences of aging. With the current presence of the first large cohort of out, trans-identified mid- to late-life individuals (i.e., trans boomers), understanding the challenges and needs of the members of this community has become increasingly important from both a biomedical and a psychosocial viewpoint. While trans people face many of the same aging-related challenges as cis individuals, trans people also have distinctive ways of experiencing the repercussions of aging.

Given the need for brevity and a lack of data, it is difficult to cover the global trans aging experiences in this entry. Consequently, this entry focuses on Western experiences, for which there are more data. It is through the lenses of gerontology and geriatrics that trans people's aging experiences are considered.

Who Are Contemporary Trans Elders?

This entry considers the age of entrance into the elder population to be 65 years. The Administration on Aging states that the U.S. population of persons 65 years or older numbered 39.6 million in 2009 (the latest year for which data are available). By 2030, it is projected that there will be about 72.1 million older persons in the United States. The National Institute on Aging global projections for the 65-years-or-older cohort are 524 million in 2010, with this number expected to increase to 1.5 billion in 2050.

It is difficult to provide an accurate estimate for the number of trans elders in the United States. There are many reasons for the absence of reliable population data on the trans elder community, including difficulties in identifying members of the population, trans people's hesitancy to self-identify as such, and trans erasure in many data-gathering instruments. As a result, identification of the trans population is challenging. Indeed, the trans-identified population is itself dynamic; in the past three decades, with the advent of more reliable surgical and hormonal interventions, more people are making the decision to transition from their birth sex or gender to an identity more consistent with who

they see themselves to be. Moreover, since 2000, some older adults, even into their 70s or later, are increasingly choosing to align their genital sex with their gender self-perception. Thus, even within the current cohort of trans elders, there is a diversity of life experience. This diversity will continue to broaden and grow as younger members of this community emerge and pioneer new labels. It is, however, possible to make some general population estimates.

Using 1999 U.S. Census data and an estimate of 3% to 7% transgender population prevalence, Tarynn Witten, a scholar in transgender aging, estimated that there were approximately 347,000 to 1,041,000 trans-identified persons in the United States over 65 years of age. Based upon more recent 2010 population estimates, Witten has argued that the U.S. population estimates should be revised to be between 1.2 and 2.8 million trans-identified individuals over 65 years of age. Others have estimated that the transgender population is only 0.3% prevalence, which means that the population estimates range from 409,702 to 1,229,106 over the age of 65. There is little information available to make population estimates for trans elder populations in other specific countries.

Social Factors in Aging

Context

Extensive research indicates that a significant proportion of today's trans-identified individuals have grown up within a biomedical and psycho-sociopolitical context of violence and abuse. Persons who identify as "gender variant" are frequently subjected to a variety of forms of discrimination (e.g., age, employment, financial, medical), stigma, sexual violence, and elder abuse, as well as hate crimes. Such discrimination has historically been reinforced by the inclusion of *transgender* as a mental disorder in the past editions of the *Diagnostic and Statistical Manual of Mental Disorders* for diagnostic classification (transgender is now replaced with the term *gender dysphoria*). Surveys of trans adults aged 50 years and older found that more than one third of respondents had experienced discrimination in health care. Eighty-three percent had suffered one or more experiences of abuse (e.g., physical, mental, financial, self, sexual), many before the age of 18 years. More than 70% had thought about or attempted suicide. Moreover, given that many of the current elders of the trans population grew up in this adverse biomedical and psycho-socioeconomic environment, they tend to be fearful and/or unwilling to interact with health care providers as well as other systems-level entities such as law enforcement or religious organizations.

Ageism and Its Consequences

Western elders are often discriminated against as a consequence of their actual chronological age or because of how old they appear. For example, some potential employers may believe that elders are "too expensive" to pay for, that elders cannot "perform" certain predefined tasks, or that they have a longer learning curve than younger potential employee candidates. Trans elders face these and additional barriers in employment. Many jobs depend upon how a person looks; consequently, "passing" may be important. Transphobia can limit job availability, thereby diminishing hiring potential.

Different age cohorts are now appearing in the trans community. Cohort effects are important in understanding ageism and other factors within the gender-nonconforming community. Trans elders often hold viewpoints that come from different life histories. For example, words like *queer* may mean different things to different generational members. This can create intergenerational conflict and thereby generate subsequent ageist perspectives that may propagate within the trans community. Complicating matters is the intersectionality of ageism and trans identity with racism and other isms. While there is increasing research concerning these intersectionalities, much more needs to be known.

Social Support Networks

There is abundant gerontological research literature supporting the importance of social networks in aging. These networks may involve birth families, legal families, families of choice, friends, individuals from various social organizations (clubs, religious organizations, service organizations, health care systems), and other support individuals such as caretakers and health caregivers. It is well known that individuals with stronger social support networks are less susceptible to the

negative consequences of aging. However, identifying as trans often profoundly affects network structures and can actually increase susceptibility by altering or reducing network structure and connectivity.

Family Structure and Function

Many of today's trans elders came out after their children had reached adulthood and left home. For some of these elders, their family members were supportive of the transition while others suffered strains and even breaks in family connectedness. Estimates from recent large cross-sectional research studies suggest that 40% of the overall community has never been married and as much as 55% of respondents have no children. Further, research by Karen Fredriksen-Goldsen, a scholar in LGBT health and aging, as well as research by Tarynn Witten, suggests that between 25% and 30% of trans-identified individuals live alone. To compensate for social network loss, many trans elders created families of choice. Yet over 30% of Witten's respondents stated that they did not know who would take care of them in the event of a major illness or when the need arose.

Religiosity/Spirituality and Faith Support Networks

The importance of spiritual/religious networks in the lives of the elderly cannot be overestimated. There is an enormous research literature on this subject. This importance is also true for those who identify as trans. However, trans identification can bring an individual into direct conflict with religious institutions, many of which see trans identities as sinful. Trans-identified individuals belong to a diverse array of religions and faiths, and issues facing religious involvement within the trans-identified community are complex. Positive religious and spiritual experiences can enhance resilience, reduce stressors, and create important social networks. Negative religious experiences can result in the opposite—heightened risk factors and more negative physical and mental health outcomes. Indeed, trans individuals have been denied funereal rights, ostracized publicly in front of their church, abused in religious nursing homes, and denied access to last rites and even to the spiritual support of their former churches.

Friendship and Intimacy Networks

As friends and family members die or move away, many elders find that their friendship support networks gradually diminish. Trans elders not only suffer these changes in network support but also lose friends and family due to their gender transition. Some individuals address this challenge by acquiring a pet. Others build networks via the Internet or by attending trans-related community events. Some simply choose to live alone. Of those who choose to live alone, research shows a significantly greater number having "feminine" gender self-perceptions than having "masculine" self-perceptions. Many elders hope that the transition will not affect those family relationships that are in place prior to transition. Rarely, however, is this the case. Transition may ultimately be associated with subsequent divorce, isolation from family and friends, and a significant degree of aloneness.

Intimacy, sexual or otherwise, is important across all ages. However, as the body ages, it is not often perceived as being as attractive as it once was. In addition to the natural processes of aging, the trans body may age in ways that make it ambiguous and uncomfortable for potential dating partners. Further, the stigma of being trans identified also diminishes the potential dating population pool. Many potential partners, upon discovering that an individual is trans identified, feel violated, and the relationship will end, sometimes violently.

One common perception of elderly persons is that they lose their desire for sexual intimacy. While age-related changes may alter sexual ability, this does not mean that it alters sexual interest and a desire for physical intimacy. In fact, many trans elders have an increased desire to experience sexuality in their new identity. This may lead to behaviors that are considered a "second adolescence." Elders of the population are frequently untrained in the important sexual protection measures for today's world, and this can lead to increased risk of HIV/AIDS/sexually transmitted infections in later life.

Sexuality is a key component of quality of life and well-being, and the need to express one's sexuality continues into old age and may even continue into nursing home or at-home eldercare environments. Caregivers in such environments may find expressions of sexuality difficult in the general elderly population and more difficult with

trans-identified persons. This can be particularly complex when the trans person has dementia or when the physical body and the gender expression do not appear to be in sync with each other.

Financial Factors in Aging

Employment barriers exist not just around chronological age (age-related bias) but also around whether or not the trans individual "passes." We do not know very much about the fiscal status of the trans-identified population as a whole. The work of Fredriksen-Goldsen and her team shows that 47.56% of her respondents were below the 200% poverty level. Witten's work showed 37% of her respondents were living below the 2013 federal 200% poverty level for a family of one person, and 56% were living below the poverty level for a family of two persons. Considering only those individuals over the age of 65, Witten's research indicated that 28.9% were living below the 200% poverty level. Moreover, Witten found that individuals with "feminine" gender self-perceptions had higher income levels than those individuals with "masculine" gender self-perceptions. Many of Witten's survey respondents stated that they did not have enough money, or had just enough money, for basic life requirements. Additionally, many felt that they were under moderate to extreme financial strain.

Retirement and Pension Planning

Like many other life phases, retirement can be complex. The differences between age cohorts and their plans for retirement are significant. Balancing the need to transition with the needs of a solid fiscal retirement can be problematic. When people think about retirement, they typically consider such things as where they will live, how they will support themselves, what kind of medical care they will be able to afford, and how they would like to live out the remainder of their lives. These are natural concerns for all individuals, trans and non-trans alike. Witten's research has shown that only 59.5% of respondents, across all ages, have a pension or other form of retirement plan and that this too varied by gender self-perception. When asked why they did not have pension plans, individuals cited underemployment, needing everything they earn just to survive, barely surviving day to day, and using retirement funds for transition expenses.

Health Care Factors in Aging

There are now many well-known considerations that contribute to a healthy and satisfying quality of life for all individuals across the life span, including trans persons.

Self-Care

Self-care is essential. Exercise (walking, bike riding, water-related exercise, and other aerobic exercises) is crucial. Maintaining a quality diet is important. Keeping cholesterol intake down, watching for fatty liver disease, not overindulging in sugary food and drink, and minimizing alcohol intake are important contributors to a better level of physical health. For individuals who take hormones, stopping smoking should be a priority. Smoking significantly increases the risk of cardiovascular and cerebrovascular events. Aging increases the risk for these events; smoking exacerbates that risk. Regular monitoring for diabetes, HIV, and colon cancer are all part of taking care of the elder trans body and should be part of regular self-maintenance. Regular oral hygiene should be part of the daily routine. As individuals age, it is increasingly possible to lose teeth because of cavities, periodontitis, and general oral infection. Tooth loss can lead to numerous negative medical consequences. While there is no research on how hormones may mediate this, research does show that simple things such as dry mouth can exacerbate oral health problems.

Medical Care

Some things require visits to a health care facility (clinic, physician's office). If one has the body part, one has to take care of it (e.g., getting regular cervical examinations and Pap smears or getting regular prostate examinations). While there are no clear-cut data on risk factors around hormone use in the trans population, research shows that hormones can influence the occurrence of breast, uterine, ovarian, and prostate cancer. Breast cancer screening should be a regular part of every individual's physical examination. Periodic screening

for osteoporosis should also be a regular part of every trans elder's physical examination. Hormones can mediate bone protection and bone loss.

It is now estimated that one in three people will develop Alzheimer's disease (AD). For trans-identified individuals, the onset of AD means eventual loss of the current identity and has severe implications for later-life care and for the well-being of the individual. Periodic monitoring for AD and other forms of dementia should be a regular part of the trans elder's medical care.

The literature on trans persons and aging documents the increased use of alcohol, drugs, and smoking with age. As individuals age, social networks begin to collapse, ageism becomes increasingly present, financial difficulties increase, and health begins to decline. Coupled with these normative factors, elders begin to face their own mortality. Moreover, along with these changes, trans persons must face questions around self-actualization. All of these factors can drive increased substance abuse as the trans person ages.

Many contemporary trans elders decided to transition or transitioned in midlife to later life. Later-life transition carries a number of additional challenges. Hormones may or may not be desired. If desired, hormone levels must be monitored carefully. There is very little research literature on mid- to later-life hormone dosing. Similarly, little is known about when to stop hormone use. Moreover, in an effort to attain more rapid transition, some elders may abuse/misuse hormones, getting them over the Internet or from illegal providers rather than seeking out competent medical supervision. Side effects of abuse can range from minor damage to loss of life.

Some trans elders desire gender confirmation surgery, while others do not or cannot afford it even if they so desire it. Surgery in midlife to later life carries with it certain additional risks due to the person's age. While age is not an exclusion from transition, age-related changes can affect the transition process. Physical changes in the body may make healing slower and can result in unsatisfactory postsurgical results. Risk of cerebrovascular or cardiovascular events may increase as well.

Mental Health Care

Gerontological literature has established that early life and life course negative events can increase later-life mortality and morbidity. Given the endemic history of violence, abuse, discrimination, isolation, and transphobia experienced by current trans elders, it is not surprising that trans-identified individuals have significantly higher rates of stress, depression, anxiety, and fear than either their LGB peers or gender-nonconforming individuals. Suicidal ideation has been shown to be significant in trans people, and suicidal ideation increases in all elders whether or not they are gender nonconforming. Some trans persons have stated that they have plans in place to commit suicide before needing to access eldercare.

Research and community reports document that today's elder trans persons have a history of suffering violence and abuse (physical, mental, financial, sexual, and verbal) across the life span. Growing older increases vulnerability to such abuse. Elder abuse can also appear in the form of not allowing elders to live as their actualized selves in eldercare facilities, disrespect, denial of hormones, outing the elder, and failure to provide needed medical attention and sharing of medical information. Research has shown that many trans elders fear what will happen to them in eldercare facilities and that they would rather live out their lives at home if at all possible.

Paying for Later-Life Care

Survey research data suggest that most trans elders expect to use some combination of personal savings and government support to pay for later-life care. Medicare Part B is the part of Medicare that covers routine preventive care. However, trans persons may face challenges in coverage when medical identification does not match gender presentation. Medicare Part D covers prescription drugs. Many elders cannot afford Part D, and problems may occur when Medicare deems hormones as not medically necessary. And because Medicare does not currently cover transition-related surgeries, these additional costs must be borne by the elder desiring them. For a number of elders, these costs come out of retirement funds.

Although it was not true in the past, military veterans are now able to obtain transition-related care through the Veterans Health Administration (VHA). All necessary preventive care, hormone therapy, mental health services, preoperative evaluation, and

postoperative care are now available to veterans. The VHA does not provide for transition-related surgeries. In some states, incarcerated individuals may be allowed to have prescribed hormones.

Legal Challenges in Later Life and at End of Life

Later-life and end-of-life challenges provide many complex scenarios for those who do not identify as trans. For those so identified, this time period may become even more complex and difficult. Transgender status can have a profound effect on many later-life and end-of-life facets. Research study data show that the trans-identified population as a whole is significantly unprepared for any sort of end-of-life issue, with less than 30% of survey respondents having advance directives or powers of attorney in place. Legal documents should detail the trans elder's wishes should they be unable to speak for themselves, detail final wishes, state who has control of the body, detail visitation rights at any medical facility, provide for one person to speak for the elder in the event that legal and medical decisions need to be made, and protect the trans elder should family relationships be strained. Other legal documents affect partners and families. Trans elders need to have carefully crafted wills and estate plans in place to protect any partnerships that developed during their lives. Wills also speak to how possessions will be distributed, and these are important, as families of choice are not protected legally without such documents. Insurance and Social Security can be problematic due to marriage laws and name changes.

End-of-Life Factors in Aging

Given the long history of negative interactions with the health care system, trans elders are very reticent to make use of traditional eldercare facilities. Nearly 40% of Witten's survey respondents stated that they had little to no confidence that they would be treated respectfully. Respondents stated worries and fears around being given the incorrect drugs, being denied hormones, being denied needed care, physical and verbal abuse, fears of being forced to leave the nursing home and becoming homeless, and not being allowed to live out the remainder of their days as their true selves. Additionally, trans elders have expressed fears that their last wishes would not be carried out. Survey respondents' concerns revolved around such things as incorrect name/gender identity on death certificates and/or gravestones. Others expressed fear that funeral directives would not be respected. Autopsy also represents a challenge, as some trans elders are not out and their true birth sex may be discovered only upon autopsy. As a result of these worries, some elders of the community have stated that they are prepared to detransition (undo as much of the previous surgeries and hormone treatments as possible), while some individuals have self-euthanasia plans in place in order to avoid having to worry about getting older.

As death approaches, many factors come into play. Pain management (palliative care) may become important, as will hospice care. Given that many trans elders are fearful of the kind of treatment they will receive during this period of life, this fear may lead to dissatisfactory end-of-life experiences for the dying and their respective family, friends, and allies. Religious/spiritual/faith needs can become critical during this time but may be problematic because of the transgender identification of the dying person. Closure events become important both for individuals who are dying and for those around them. Self-identity may be lost due to dementia, creating a strain for support staff and families. Delirium may cause confusion and inhibit the ability to meet someone's final needs. Much research needs to be carried out in this area. We also know little about end-of-life issues for trans elders in Veterans Affairs facilities or for those who are incarcerated.

For families of trans elders, death can also be difficult. Numerous gender-related questions become important. Should the funeral be open or closed casket and, if so, how should the deceased be dressed? Funeral ceremonies can become challenging not just from the perspective of how to refer to the deceased but also from the perspective that some religious organizations believe that being transgender is a sin and refuse to allow ceremonies to take place in their facilities or to allow the deceased to be buried in their graveyards. Obituaries can become challenging when one considers how to refer to the gender of the deceased. Legal control of the body and of various postdeath decisions can also be complex when considering

whether the family of origin versus the family of choice has final legal decision-making power.

Conclusion

As seen through the lenses of geriatrics and gerontology, it is evident that aging is a complex, multilevel process that involves many challenges. Identifying as trans adds to those challenges. Today's trans elders have endured a history of violence, abuse, discrimination, and denial of care that still persists. Notably, this is particularly true for African American trans women. Trans identification can lead to a multifaceted state marked by depression, sadness, loneliness, anger and frustration, anxiety, regret, feelings of loss, and decreased levels of happiness. In addition to psychological stressors, trans and gender-nonconforming people are frequently at increased financial risk. Financial stability may be sacrificed due to lack of employment or the high cost of surgeries. Loss of a job can undermine a relationship or family, leading to anger, resentment, frustration, depression, and isolation. The body of literature on trans experiences of later life and end of life is relatively new and still growing. As younger cohorts move into middle and old age, many more questions will need to be answered. There is still much to learn about patterns and implications of the aging transgender life course.

American Civil Liberties Union

The American Civil Liberties Union (ACLU) is a not-for-profit civil rights and civil liberties organization that was founded in 1920. For more than 100 years, the ACLU has worked in courts and legislatures to defend the U.S. Constitution and U.S. civil rights laws. Although perhaps known best for the organization's free speech work, the ACLU was one of the earliest defenders of trans rights in the United States. It continues to advocate and bring pioneering litigation to further gender justice in areas such as access to employment, restrooms and other single-sex facilities, health care, and athletics, as well as with respect to the treatment of prisoners and detainees.

In the first half of the 20th century, the ACLU's work on behalf of LGBTQ people often focused on challenging criminal restrictions on expressions of gender and sexuality outside of heterosexual norms. The first LGBTQ case that the ACLU took on was a challenge to an attempt in 1936 to ban a theatrical performance of Lillian Hellman's play, *The Children's Hour.* When the play's producers sought to hold a performance in Boston, the city's mayor informed them that the play's "lesbianism" violated "community standards." The ACLU represented the producers in a suit in federal court. Although the lawsuit did not address trans issues directly, it was the start of a long history of defending the rights of people to live and express themselves authentically in life and in art.

In 1967, the ACLU worked with the Redd Foxx Club, a bar in Los Angeles that hosted performances by Sir Lady Java, a well-known trans performer. At the time, a local law made it illegal for someone to dress as a person of the "opposite sex." The Los Angeles police threatened to arrest the owner of the Redd Foxx if Sir Lady Java continued to perform. The ACLU threatened litigation if the police did so. As in these two cases, the ACLU often defended the rights of LGBTQ people against government censorship and criminalization in the 20th century.

Most of the ACLU's work in support of trans people has been in the 21st century, as the organization has increasingly prioritized LGBTQ advocacy work generally and trans advocacy work specifically. While the majority of national LGBTQ legal organizations, including the ACLU, focused on marriage equality for same-sex couples from the early 2000s to the Supreme Court's *Obergefell v. Hodges* decision in 2015, the ACLU also pursued pivotal trans rights cases in federal court throughout this period. For example, in 2001, the ACLU achieved an important district court victory in *Hyman v. Louisville,* defending the validity of a Louisville, Kentucky, ordinance prohibiting discrimination based on sexual orientation and gender identity. This case foreshadowed the growing number of challenges to trans-inclusive nondiscrimination policies in the 2010s.

Between 2005 and 2009, the ACLU litigated the landmark federal case of *Schroer v. Billington* under Title VII of the Civil Rights Act and the U.S. Constitution. The case involved a woman who is trans and was hired by the Library of Congress when they thought she was a man and then had her job offer rescinded when she informed her future employer that she is a woman and would be

starting the job consistent with her true gender. The case was instrumental in continuing to advance the argument that anti-trans discrimination is sex discrimination under federal civil rights laws.

The arguments that the ACLU and other legal groups developed over decades to protect trans people from discrimination culminated with the Supreme Court ruling in three cases in 2020 that sex discrimination under federal employment law includes discrimination based on gender identity and sexual orientation. The ACLU was counsel for two of the three plaintiffs before the court. One case involved a woman who, like Diane Schroer, lost her job just because she was trans. Aimee Stephens was fired when her employer learned of her gender identity; this led to financial hardships and disruptions in her health care that tragically resulted in her premature death from kidney disease while her case was pending before the Supreme Court.

The ACLU has been involved in other Supreme Court cases defending the rights of trans people, beginning with the 1994 pivotal prisoner rights case, *Farmer v. Brennan,* brought by Dee Farmer, a Black trans woman in federal prison, who had been repeatedly beaten and raped after being incarcerated in a prison for men. The ACLU represented Farmer at the Supreme Court, which ruled that ignoring the risk of serious harm to prisoners violates the Constitution. In lower federal courts, the ACLU has also secured critical wins for trans prisoners, including in the case of *Fields v. Smith,* which struck down a Wisconsin law restricting state spending on health care for trans prisoners. These cases have set important legal precedents in protecting trans prisoners across the country.

Between 2015 and 2020, the ACLU increased its legislative advocacy and litigation on behalf of trans people, particularly trans youth. The organization lobbied state legislatures to prevent the enactment of laws restricting the rights of trans people to access public spaces and health care. When, in 2016, North Carolina passed a law that required people to use the public restrooms matching the gender marker on their birth certificates, the ACLU and Lambda Legal immediately filed a lawsuit to block the measure. Likewise, in 2020, when Idaho passed a law banning trans student athletes from participating in sports according to their gender identity, the ACLU quickly sued. Over the years, defending the rights of trans people to live authentically and with dignity has become a central part of the ACLU's work.

With a broad network of advocates and significant resources, the ACLU has been a leader in the fight for trans justice. The organization's LGBT and HIV Project, which includes four out trans attorneys, is helping to lead its work and vision moving into the group's next hundred years.

Ancient and Medieval Times

In the Western imagination, trans people are closely associated with modern medical techniques such as hormone therapy and plastic surgery. People therefore often assume that being trans is a product of modern medical science. However, the notion of a strict gender binary is not held by many traditional cultures around the world. The history of Europe and the Middle East is also full of examples of people living gender-diverse lives. This entry will show

that trans people have existed throughout history and that being trans is therefore presumably part of the human condition.

Mesopotamia

We begin in the 23rd century B.C.E. in Ur, one of the oldest cities in the world. A hymn to Inanna, attributed to the Sumerian princess Enheduanna, claims that the goddess has the power to "turn a man into a woman and a woman into a man." It is unclear what this means and how such powers would have affected ordinary Sumerian life. However, a description of a festival in honor of Inanna talks of celebrants wearing men's clothing on the right side of their body and women's clothing on the left. An inscription on a statue fragment refers to a devotee of Inanna called Silimabzuta, who is described as a "person-man-woman." Clearly, some level of playing with gender was central to the worship of Inanna. Inanna, known as Ishtar in Babylon and Assyria, continued to be worshipped for over 1,500 years until the rise of the Persian empire and the arrival of Alexander in the Middle East. Similar goddesses were worshipped in the region throughout the Roman period.

Ancient Rome

Cybele Comes to Rome

There are few obvious examples of gender diversity in the early history of Europe, but things changed significantly in 204 B.C.E., when Rome enlisted a foreign goddess in its fight against its rival Carthage. Following the advice of an oracle, Rome purchased a statue of a goddess called Cybele from the country of Phrygia in modern Turkey. She was installed with great honor in the city. As Magna Mater (Great Mother), she became a major feature of Roman religious life, despite the behavior of her devotees being distinctly un-Roman in their transcendence of gender norms.

Among the worshippers of Cybele were people called Galli. They were assigned male at birth but were castrated and lived as women. They often worked as beggars, and historians have drawn parallels to the *hijra* of modern India. Popular imagination has it that the Galli castrated themselves, perhaps with a flint knife as described in Catullus's Poem 63, but safe castration was a common feature of Roman medicine. A medical instrument found in the Thames and now in the British Museum is thought to have been used for the safe removal of testicles by the local temple of Cybele.

Views of the Galli

By Imperial times, the cult of Cybele was well established in Rome with a temple on the Palatine Hill, next to the Imperial Palace. But many Romans, perhaps especially the elite men who have provided most of the surviving written records, did not approve. The satirist Apuleius, in his comedy *The Golden Ass,* described them in a way reminiscent of a troupe of modern-day drag queens.

Philo of Alexandria, a Jewish historian from Egypt in the period of Roman rule, gives a description closer to that of modern trans women. He refers disapprovingly to people who "have desired to be completely changed into women and gone on to mutilate their genital organs" (*Special Laws,* 3:41).

Around the time that Philo wrote, Jesus of Nazareth was preaching in Judea. The Apostle Matthew records that Jesus held forth favorably regarding eunuchs, including those who have castrated themselves for religious reasons. This comment was to have major implications for early Christians, but at the time, Jesus could have only meant people like the Galli as they were the only ones being castrated in this way.

The Galli and the Law

One of the earliest references to a Gallus is a legal case from 77 B.C.E. involving a disputed will. One Genucius had been left money by a friend. The will was challenged, and a magistrate upheld the challenge as under Roman law, only men and women could inherit. Genucius, as a Gallus, was neither.

Under Roman law, a eunuch could not be a citizen. Roman citizens had substantial legal privileges denied to noncitizens, so any citizen wishing to become a Gallus would be sacrificing a lot more than body parts. The status of the Galli received a significant boost under the Emperor Claudius (41–54 C.E.) who added the Rites of Attis to the official Roman religious calendar. Attis, the subject of Catullus's Poem 63, was said to have been the

first person to castrate himself in honor of Cybele. This meant that there was an official day (March 24) on which Roman trans women would have their surgery, and it was a religious holiday.

Roman society gradually became less brutal in some ways with time, and attitudes toward castration changed. Domitian (81–86 C.E.) banned the castration of children, and Hadrian (117–138 C.E.) allegedly banned all castration, even if it was voluntary. This might have been an issue for the cult of Cybele, but evidence from the time of Hadrian's successor, Antonius Pius (138–161 C.E.), suggests that it was still possible to buy a castration permit. Hadrian had not banned castration; he had taxed it.

Elagabalus and Sporus

In 218 C.E., a 14-year-old known as Elagabalus unexpectedly became emperor thanks to political machinations following the assassination of Caracalla. Growing up in the region we call Syria, Elagabalus had become a devotee of local religions and had a more flexible attitude to gender than did the conservative Romans. Contemporary historians described the young emperor as dressing in women's clothing, flirting with palace guards, and marrying a male charioteer. Cassius Dio states that a substantial reward was offered to any physician who could provide Elagabalus with a vagina.

Martin Icks, in his biography of Elagabalus, notes that Dio was writing after the assassination of the young emperor and had every reason to invent scurrilous rumors. Nevertheless, it seems clear that Elagabalus was someone who was dealing with personal gender issues and, by modern standards, may have identified as female.

This, however, was not the first reference to possible vaginoplasty in Roman history. In 67 C.E., the Emperor Nero married a young person known as Sporus. We are told that Sporus was castrated, and Nero offered a substantial reward to any surgeon who could make his new wife fully female. In *The Twelve Caesars,* Suetonius uses the phrase "*in muliebrem naturam transfigurare*" (transform into a natural [woman]), which may be the first use of the term *trans* in such a context (Suetonius, n.d., 28:1).

Modern historians view the story of Sporus with horror, talking of a helpless victim of the cruel and capricious Nero. Yet contemporary sources show Sporus embraced the role of empress and was provided with education on how to behave like a high-class Roman woman. Nero and Sporus went to Greece on holiday, where the crowds wished them a happy life and many children.

Sporus was one of a small group of loyal companions who went with Nero when he fled Rome fearing assassination. The emperor eventually took his own life, but his companions were captured. Rather than be killed as we might expect, Sporus became a pawn in the battle for succession, being courted by two of the claimants to the throne. This suggests that even elite Roman men saw Sporus as having some of the cachet of an empress.

Intersex in Rome

Roman society seems to have been comfortable with the idea of people "changing sex." Stories of such transformations appear in mythological tales, several of which are featured in Ovid's narrative poem, *Metamorphoses.* Some writers, including Pliny, claim to have met people who had transformed. Romans would have been more familiar with intersex people than we are today, as births took place in the home and there was no option for obviously intersex babies to be surgically altered.

Early Roman law gave fathers the right to kill any baby that they deemed deformed, but attitudes softened through history. In the Roman Republic, intersex people might be sacrificed to appease the gods in the case of a bad harvest or a lost battle. However, older intersex children are mentioned, suggesting that at least some Roman parents protected their offspring. By the time of the Empire, anyone with an unusual body was potentially valuable as an exhibit in the theater or an interesting slave that wealthy Romans could show off to their friends.

The most famous intersex person from Roman times is the philosopher Favorinus, who is described in *Lives of the Sophists* by Philostratus as follows: "He was born double-sexed, a hermaphrodite, and this was plainly shown in his appearance; for even when he grew old he had no beard; it was evident too from his voice which sounded thin, shrill, and high-pitched, with the modulations that nature bestows on eunuchs also" (Philostratus, n.d., 23).

Historians have suggested that Favorinus exhibited Reifenstein's syndrome and would not have gone through male puberty. Despite this, he became

a court favorite of Hadrian and was well known throughout the Empire. This speaks volumes for his skill as a philosopher and perhaps some shifting of Roman attitudes toward gender diversity.

The Rise of Christianity and the Medieval Period

When Christianity became the state religion of Rome, all other beliefs, including the worship of Cybele, fell on hard times. The early Christians took a stern line on sexual morality. Indeed, it is thanks to Christians that we know of the existence of castration permits. A man who is castrated cannot fall into sin, and Jesus had spoken favorably of those who castrate themselves for the Kingdom of Heaven's sake.

With time, the idea that becoming castrated made you more holy took hold in the Christian church. In the Byzantine Empire, it was common for monks to be eunuchs. This, in turn, made space for other forms of gender diversity. There are several tales of assigned female people who entered monasteries and lived successfully as men for many years. This would have been much easier to do if a high-pitched voice and lack of beard could be explained by castration.

One example is the life of Saint Euphrosyne, as told by an English monk, Ælfric, in his *Lives of the Saints*. A resident of Alexandria, Euphrosyne escaped an arranged marriage by entering a local abbey claiming to be a eunuch called Smaragdus. Ælfric effortlessly switches pronouns at the point of gender transition and refers to Smaragdus as male from then on.

The Story of Silence

This 13th-century story, written in French, is an Arthurian romance. It is set after Arthur's time, but Merlin has a major role. Silence is the child of the Duke of Cornwall and is raised as a boy to provide the duchy with a male heir. An excellent warrior, Silence earns a place at court where the lustful queen takes an interest in the handsome young knight.

During the story, Silence is beset by the opposing voices of Nature and Nurture. Nature insists that Silence was born a girl and should accept the truth of that. Nurture insists that Silence enjoys being a knight and would be foolish to give up the social advantages that masculinity provides. The discussion of gender roles and stereotypes seems remarkably modern today.

Eleanor Rykener

In 1395, the mayor of London was asked to try the case of a sex worker. The accused wore women's clothing and used the name Eleanor Rykener but was discovered to have a penis and also used the name John. Given that Rykener was doubtless hoping to minimize any punishment, it is hard to infer much about identity from the court transcript. Rykener did claim to have had female clients as well as male, but being Eleanor was not a one-off. Female friends had allegedly helped Rykener with clothing and to develop a convincing female personality. Rykener also claimed to have worked doing embroidery, and as a barmaid, while living as Eleanor.

Ancient/Medieval Times, Jews and Judaism

Although it is anachronistic to apply modern constructs of sex and gender to earlier times, one can state that the classical texts of Rabbinic Judaism discuss gender ambiguity, gender transition, and other relevant topics. The texts reveal that throughout the ages, rabbis have been aware not everyone fits a gender binary. They categorized and classified a number of gender constructs beyond male and female and explicitly discussed whether their intersex constructs were independent constructs or subcategories of female and male. Gender transition is discussed in some of the texts. There are also textual records of discussions relevant to topics such as deadnaming, crossdressing, and castration.

Rabbinic Gender Constructs

The gender binary and nonbinary challenges to it are found in rabbinic texts from late antiquity and onward. Biblical exegesis explores intersex individuals and gender transition in biblical narratives. While the Babylonian Talmud (sixth or seventh century C.E.) contains many such discussions, it also records third-century C.E. sage Abba Arikha as saying that everything is created in the binary as either male or female.

The rabbinic corpus tends to try to force the nonbinary gender constructs it derives from both biblical narrative and actual bodies into a binary system. Ancient and medieval rabbinic Judaism was a heavily gendered religion, and as such, it was seen as imperative to delineate the sexes so as to know which gender construct applied to any given individual. Following the discourses of their time, these texts do not distinguish between gender and sex.

Using biology as their authors understood it, the rabbinic texts offer an array of gender constructs based primarily upon phenotyping of external genitalia and the development (or lack/delay thereof) of secondary sex traits. Beyond female and male, the four main Jewish gender constructs present in Jewish texts from late antiquity and onward are *androgynos, tumtum, saris,* and *aylonit*.

Androgynos

Rabbinic society defined *androgynos* as someone who externally appears to possess at least some portions of both female and male genitalia. Androgynos is the only nonbinary gender construct that the Mishna (the first authoritative collection of texts embodying the oral tradition of Jewish law) explicitly says may be a distinct gender. As they were generally perceived as ambiguously both male and female (and not a third gender), the texts state androgynos were required to uphold both the strictures imposed upon males and those imposed upon females. *Androgynos* is a Greek loanword, indicating Jewish concepts of gender did not develop in isolation.

The Tosefta and the Mishna (both second century C.E.) compare and contrast androgynos with males and females. Among the various behaviors codified for androgynos was that a marriage to a woman may be valid but not one with a man. The Babylonian Talmud quotes one sage who says the biblical prohibition of a man lying with a man as he does with a woman is not about male–male relations but instead prohibits males from having vaginal intercourse with androgynos.

A fifth-century C.E. midrash (literally, "textual interpretation"; ancient commentary on part of the Hebrew scriptures) states humanity was initially a single androgynos being before being split into a male Adam and a female Eve. While there are alternate understandings of the creation narrative, the 11th-century C.E. Rabbi Solomon ben Isaac (Rashi) included this in his biblical commentary.

Tumtum

A *tumtum* is generally understood as someone with no clearly visible external genitalia, which some ancient texts say is due to a layer of skin covering their genitals. The Mishna says removing this skin can reveal their gender. One Talmudic opinion classifies someone with descended testicles but no visible penis as a tumtum, although other texts categorize such individuals as *saris hamma*. The Mishna states a tumtum is either male or female, but so long as their genitalia are not visible, their gender is indiscernible. The texts say a tumtum must follow the religious strictures of both males and females. Some read the Talmud as saying tumtum is a distinct gender.

The Talmud offers an understanding of the biblical characters Abraham and Sarah as *tumtumim* who could only have children after divine intervention to clearly render them as male and female.

Saris

Saris is generally translated as eunuch and in classical rabbinic texts is divided into two subcategories, *saris hamma* and *saris adam,* meaning someone born a saris or someone who became one later in life. This category includes those identified as male at birth who are lacking or have damaged some portion of their genitalia, and some include any man who is congenitally infertile or perhaps impotent. The medieval texts indicate that a saris may undergo traditionally female development at puberty. In the biblical narrative, eunuchs were often royal servants, and sometimes their gender status allowed them to interact with women in ways that other males were not.

Aylonit

An *aylonit* is someone identified as female at birth who never goes through puberty, has a significantly delayed puberty, is congenitally infertile, or only develops male sex characteristics upon reaching puberty. The Talmud offers the possibility that the biblical matriarch Sarah was an aylonit as an explanation for why she did not bear a child in her younger years. While generally coded as female, there are divergences predominantly relating to marriage and intimacy.

Other gender constructs are sometimes discussed in modern literature as rabbinic genders, but Jewish texts through the Middle Ages view them as clearly either male or female. The texts do apply gender role restrictions (especially pertaining marriage), which could imply they are coded as incomplete males or females. The most discussed of these is that of an *isha katlanit* (Hebrew for a deadly woman), who is forbidden from remarrying if she has been twice widowed.

Transition

From works of late antiquity such as midrashim and the Talmud to medieval poetry and works of kabbala, or mysticism, there are multiple cases of gender transition present in classical rabbinic texts.

As was mentioned above, Midrash Rabba offers the possibility that Abraham and Sarah were tumtums until divine intervention provided them with male and female genitalia, rendering them fully (in the eyes of the rabbinic texts) male and female.

The Talmud discusses a few cases of gender transition. In discussing the birth of Dina to Leah in the biblical narrative, the Talmud explains that originally Leah was pregnant with a boy, but she believed that if she had another son, that would mean her sister Rachel would not have another son. The Talmud says that upon this realization, she prayed to have a daughter and not a son, and her fetus was then changed in utero from male to female.

The Zohar (a 13th-century C.E. kabalistic work) conceives of God as androgynous, just as Adam was before Eve was split off. Since it understands humans should try to emulate God, it instructs everyone to strive to be simultaneously male and female despite our gendered bodies.

The desire to possess different genitals than those one is born with is expressed in a poem by Kalonymus ben Kalonymus. While scholars debate if this was sarcasm, the poem demonstrates at least some space for discussion of gender transitioning in the 14th century C.E. In the 16th century C.E., Rabbi Yosef Karo described human souls as either male or female and wrote of cases where the gender of a soul differs from the gender of the body it inhabits.

Most of the gender transitions discussed in ancient and medieval Jewish texts were supernatural and without physical human intervention. The exceptions are the castration of eunuchs and removing the flap of skin over the tumtum's genitals.

Relevance to Modern Trans Understandings

Rabbinic texts of antiquity and the medieval era raise several other issues brought up in modern Jewish discussions of trans topics. These include prohibitions on crossdressing, castration/sterilization, and deadnaming, as well as texts highlighting the value of human life. Although relevant to trans inclusion, not all of them are so contextualized in classical rabbinic texts.

Crossdressing

Antique and medieval rabbinic biblical reception understood the biblical text as prohibiting a man from wearing women's clothes and vice versa. Classical rabbinic texts convey debates about exactly what is included in this prohibition and under what circumstances it may apply. It may have included using or wearing another gender's clothes, tools, or ritual items. It may prohibit women using weapons and armor or men removing their body hair in certain or perhaps all manners.

Some medieval texts had narrower understandings of the prohibition. Rashi Shlomo Yitzhaki says that the prohibition actually only applies in cases meant to deceive people for illicit sexual relations, and some of the medieval texts actively permit crossdressing for the holiday of Purim, during which celebrants may wear costumes based on characters in the biblical Book of Esther. Rabbi Maimon ben Maimon (Maimonides, also known as the Rambam, 12th century C.E.) understood the prohibition as part of avoiding paganism, thus possibly leaving room for crossdressing to be permitted when not related to idolatry.

Castration/Sterilization

Sifra (2nd century C.E.) and the Tosefta understand Leviticus as prohibiting Jews from damaging, sterilizing, or castrating male and possibly also female reproductive organs. The Talmud discusses whether drinks causing sterilization are permitted. The Talmud also discusses whether an act that would otherwise cause male infertility remains prohibited if one already is infertile. Maimonides does not permit physically damaging male or female reproductive organs, but he does permit women to consume sterilizing compounds.

Deadnaming

The biblical narrative includes several cases of name changes. In some cases, such as Abraham and Sarah, the texts say one should not call them by their original names. One Talmudic sage says his life was extended because he only called people by their correct names. Midrash Tanhuma states that names can influence people's behavior and direction in life, and the Talmud gives examples of this. Some learn from Adam's naming of the animals that names are holy and eternal and thus advocate that while one can add or alter names, they should not entirely abandon their original name, but other sources allow one to do so. The Halakhic codes (Jewish law and jurisprudence, based on the Talmud) indicate that one's legal name remains whatever people call them but recognize that even if only a minority of people accept a new name, it can take precedence as the primary name, although the old name may not be fully eradicated until everyone has ceased using it. The midrash teaches that only after changing the names of Abram and Sarai to Abraham and Sarah were they able to have children, and if one reads this together with the midrash that they underwent gender transition, it may be a late antiquity story of name change accompanying gender transition.

Pikuach Nefesh

One of the key principles in Jewish texts from late antiquity onward is that of *pikuach nefesh,* preserving human life. The Mishna says saving a single life is akin to saving the whole world. The Talmud says one may violate any of Judaism's behavioral norms except for murder, idolatry, and having certain illicit sexual relations in order to save a life. The Mishna says norms may be violated even if it is unsure that doing so will save a life or even there is only a chance life is at risk. The Talmud says pikuach nefesh applies not only in cases of physical threats but also in mental and emotional ones. While pikuach nefesh is not applied to transitioning or trans inclusion in premodern eras, modern scholars reference these texts in deliberating whether to permit activities otherwise discouraged in Jewish tradition.

Androgyny

Androgyny has had a variety of definitions throughout history in different fields of study. Within psychology, androgyny most commonly refers to gender expressions that incorporate both "masculine" and "feminine" traits. What traits are deemed masculine or feminine is determined by societal norms and differs across cultures; therefore, androgyny may have different meanings in different cultures and over time as gender roles change. Androgyny and its adjective form *androgynous* have also been used less frequently by some as a gender identity. An androgynous gender identity refers to an identity including both masculine and feminine characteristics and would most likely fall under the umbrella of nonbinary gender identities. In the past 20 years, *androgynous* has also been used by some interchangeably with the term *gender nonconforming* to refer to those whose gender expression or presentation differs from societal expectations based on one's sex assigned at birth. Androgyny is a relevant concept within trans communities because many identify with having androgynous gender expressions or identities, and androgynous gender expressions are often the target of stigma, harassment, and violence.

The term *androgyny* stems from the Greek roots *andro* (male) and *gyn* (female). The adjective *androgynous* dates to the early 17th century and was derived from the term *androgyne*—used in the 14th and 15th centuries in France and England. *Androgyne* is a term used today and typically refers to nonbinary people with androgynous gender expressions. Historically, androgyny and androgynous often referred to people or animals with a combination of "male" and "female" physical sex characteristics and have since been replaced with the term *intersex*.

Androgyny has existed throughout history and is found within every culture. In many cultures in ancient history, individuals with androgynous traits were viewed positively and at times idealized by ancient Greek myths. Many non-Western cultures embraced and/or continue to embrace androgynous community members and recognize gender identities outside of the gender binary, such as *tumtum* in Jewish culture or *hijra* in East Indian culture. Androgyny became stigmatized during the rise of Christianity and in the era of European colonialism beginning in the 12th century, when androgyny was associated with same-sex desire, which became highly stigmatized.

Androgyny in Psychology

Sandra Bem is thought to have popularized the concept of androgyny in the field of psychology with the development of the Bem Sex-Role Inventory in 1974, one of the most widely used measures of gender expression. The measure classified individuals into one of four gender role orientations: masculine, feminine, androgynous, or undifferentiated. According to this measure, a feminine individual was defined as someone who ranked high on feminine traits and low on masculine traits, a masculine individual ranked high on masculine traits and low on feminine traits, an androgynous individual ranked high on both masculine and feminine traits, and an undifferentiated individual ranked low on both masculine and feminine traits. Bem's work separated masculinity and femininity into two dimensions that allowed for people to hold combinations of both rather than one spectrum in which femininity and masculinity were seen as opposing one another. Bem hypothesized that androgynous individuals were more flexible and mentally healthy compared with those of other gender role orientations and that androgyny would contribute to more effective

leadership and parenting styles. However, these hypotheses have not been substantiated by subsequent research.

Androgynous Expressions

The social acceptability of androgynous gender expressions and presentation has changed over time, with androgyny becoming more socially acceptable, especially among women. Strict gender roles shifted in the 1960s and 1970s, coinciding with feminist movements that fought to change gender roles, particularly of women in the workplace and at home. Some women intentionally changed their gender expression to be more masculine as a political statement that women should be treated as equal to men. Also, at this time, popular musicians such as Elvis Presley, Jimi Hendrix, and David Bowie departed from conventional masculine norms by performing in flashy, androgynous costumes and stage makeup. However, these popular figures did not necessarily increase the acceptability of androgyny in men as effeminate men continued to be highly stigmatized.

Discrimination and Prejudice

Androgynous and gender-nonconforming expressions have been associated with LGBTQIA+ communities, and research has found a strong correlation between gender nonconformity and having an LGBTQIA+ identity. However, this correlation does not indicate causation; gender nonconformity does not dictate someone's sexual orientation or gender identity or vice versa. Research thus far has found that gender-nonconforming LGBQ individuals are at increased risk of discrimination, victimization, and harassment compared with gender-conforming LGBQ individuals, thus also increasing their risk for psychological distress and mental health concerns. It is unclear whether gender-nonconforming individuals are targeted because they are perceived as LGBQ or because of discomfort with gender nonconformity.

Androgynous gender expressions, which may lead to gender ambiguity, have also been associated with increased risk of stigma and violence toward trans people. As such, many trans individuals' practice "hyperfemininity" or "hypermasculinity" to avoid being targets of violence. There is emerging evidence suggesting that nonbinary people may be at even higher risk for harassment compared with trans men and trans women. Some have hypothesized that this finding may be explained by stigma toward androgynous gender expressions. However, more research is needed to understand this finding.

Misconceptions About Androgyny

Nonbinary people have gained more visibility and more social acceptance than in the past. With this visibility, more stereotypes and misconceptions have emerged about nonbinary people. One major stereotype is that nonbinary people look androgynous, which is true for many but not for all nonbinary people. This stereotype has led to feminine and masculine nonbinary people feeling invisible and that their identities are more likely to questioned or invalidated. Additionally, androgyny in mainstream media has often been represented by white, thin, masculine individuals who were assigned female at birth. Other androgynous individuals outside of these identities still feel highly stigmatized and excluded from spaces that only accept certain types of androgyny.

Anti-Trans Theories

Gender is one of many facets of diversity, and depathologizing gender is the focus of ongoing advocacy efforts. Historically, cisgender (cis) individuals have misunderstood and poorly conceptualized gender dysphoria in academic literature, which in turn has perpetuated views that trans individuals' gendered experiences are illegitimate and invalid. Instead of recognizing gender identity and expression as a human right and diverse experience, theories have emerged to maintain a sociocultural hierarchy and to further stigmatize trans individuals (e.g., medically transitioning is a necessity in order to conform, to fulfill a sexual fetish or deviant need, and/or to follow a current trend to fit in with peers). This entry discusses two anti-trans theories that have been a source of significant criticism and debate: rapid-onset gender dysphoria and autogynephilia. The entry entails a description of the theories, select criticisms of these theories, and a discussion of where these theories stand today.

An Anti-Trans Theory Related to Youth: Rapid-Onset Gender Dysphoria (ROGD)

Rapid-onset gender dysphoria (ROGD) is a concept that originated in 2016 on three blog sites (4thwavenow.com, youthtranscriticalprofessionals.org, and transgendertrend.com) that are known to be critical about affirming trans identities. *ROGD* is a term developed to describe parents' experiences with a child coming out as trans suddenly during adolescence after being involved with trans-oriented social media or being pressured by trans-identified peers. The involvement by young trans individuals in trans-related media content and peer relationships prior to coming out was used as evidence for a "social contagion" or a trend-like phenomenon to delegitimize youth's gender identities. In February 2017, a poster abstract on ROGD by Lisa Littman was published in the *Journal of Adolescent Health,* which marked the first instance of ROGD being included in an academic source. Consequently, this abstract's publication elevated this line of discourse to the academic literature, paving the way for subsequent references and citations. As a result, an empirical journal article soon followed by the same author, appearing in *PLoS One*. This article suggested that ROGD is a new clinical presentation of gender dysphoria primarily affecting trans boys and trans masculine adolescents around puberty. Since its appearance in the academic literature, other scholars have critiqued this argument as being methodologically flawed and indicative of a trans myth. The timeline of developments in the discussion around ROGD has been well captured by a number of other authors, including Julia Serano and Zinnia Jones.

A scientific critique of this study is that it violates principles of research methods by using a pathologizing framework and language. For example, Littman uses terminology (e.g., cluster outbreaks) that promotes the conceptualization of gender dysphoria and identification as trans as a contagious disease or disorder. The aims provided in the article are as follows: "(1) to describe an atypical presentation of gender dysphoria occurring with sudden and rapid onset in adolescents and young adults; and (2) to generate hypotheses about the condition, including the role of social and peer contagion in its development." Likening trans identities to a disease is in conflict with national and international organizations whose positions clearly state that identifying as trans is not a mental disorder (e.g., the American Psychiatric Association, the World Professional Association for Transgender Health, and the World Health Organization). As such, bias appears to be present from the basic premise of the study and continued through each stage of the research process.

Select Criticisms

ROGD has been critiqued as anti-trans propaganda and bad science. ROGD is not recognized in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*) or the World Health Organization's *International Classification of Diseases* (*ICD*), although late-onset gender dysphoria is an existing clinical subtype that is present in published literature and diagnostic manuals, such as the *DSM-5*. In both implicit and explicit ways, the conceptualization of ROGD pathologizes a young person's gender exploration and identity. ROGD suggests that a young person is influenced by larger social trends or is going through a time-limited phase, rather than

their identity exploration process being a valid and authentic gendered experience. Concerningly, if future publications are framed from a ROGD conceptualization and draw on similar language (e.g., "rapid onset"), then this literature could be used as evidence and a justification to restrict access to critical gender-affirming interventions, peer interactions, and information/knowledge to assist with gender literacy. For example, a parent whose adolescent child is actively exploring their gender identity may refuse to help their child connect with health providers or attempt to limit their social interactions with supportive and affirming peers and other important adults (e.g., teachers) if they believe that such activities could contribute to the "rapid onset" of a trans identity.

Beyond the conceptual critiques of ROGD, numerous other critiques have been made regarding the science behind this theory. That is, the methodology used to collect data and analyze findings was fundamentally flawed in a number of critical ways, contributing to weak and biased results. First, self-selection bias was a concern of the recruitment process. The consent form described the social contagion premise, despite it not being a criterion for study inclusion. Describing the study in this way could motivate specific groups who agree with the premise to choose to participate. Sampling bias was also evident in that the 256 participants were solely recruited from the three aforementioned trans-critical websites whose readership included parents who used the websites to share experiences of their children that were consistent with the concept of ROGD. As a result, the study sample only included parents who, from the start, were skeptical of their child's gender identity and felt like ROGD may apply. Recommendations regarding best practices in sampling and recruitment, which would maximize generalizability of study findings, would necessarily involve random sampling from the general target population. Although trans populations (and, consequently, family members of trans participants) are considered hard to reach given their continued relative invisibility in societal institutions (e.g., not collecting data beyond "male" and "female" in many institutional settings), sampling should nonetheless focus on reaching a broad, and as random as possible, range of members of the target population. In this study, however, only a specific subset of the larger target population—parents or caregivers of trans youth—were recruited and who represented a narrow sociopolitical stance, which results in profound sampling bias.

Littman's study was descriptive and used an online quantitative and qualitative design. Littman created the 90-item survey but did not provide psychometric properties of survey items; in turn, the reliability and internal validity of the measure are unknown. Moreover, science scholars have long pointed to the common reliance on statistical significance as suggesting that a theory is true as one of the most flawed and scientifically unsound practices to emerge in the social sciences. Psychological theories, such as those regarding gender, need to be rigorously evaluated using best practices in methodology and statistical analysis, through replication, and by testing alternative explanations. In this regard, the early research of ROGD falls well short.

Another critical concern in the methodology underlying Littman's ROGD paper is that although the parents themselves who were sampled may have been surprised by their child's trans identity or felt that their identity development was rapid or abrupt, data from the youth themselves were not collected. Importantly, this sampling decision reveals an important gap concerning the parents' accurate perception of their child's gender identity. That is, the youth themselves may not have experienced their gender identity development as rapid or a sudden onset. Rather, they may have chosen to not disclose their trans identity to their parents or caregivers for a variety of reasons, which could include confidence, feeling unsafe, worry of family rejection, and only just recently gaining the language to describe their experience.

What Has Happened Since the Publication of the Term ROGD?

Since Littman's original publication, the editor-in-chief of *PLoS One* has offered a written apology to the trans and gender-diverse community, along with an explanation that a postpublication review of the Littman article was conducted. Through this review, the study and results were deemed a valid contribution to the scientific literature, and Littman revised the paper to address concerns regarding the study's title, abstract, purpose, methodology, and

conclusions. For example, some updates to the article include providing more detailed descriptions about recruitment methods and sites, a stronger emphasis that the study is solely based on parental observation, additional discussion of ROGD and late-onset gender dysphoria, and further discussion of limitations and biases. The subsequent revision was therefore republished.

However, leading international trans and psychological health associations (e.g., World Professional Association for Transgender Health, the Australian Psychological Society, and the Australian Professional Association for Transgender Health) published official statements noting that ROGD is not currently recognized as a clinical phenomenon. These statements also emphasized that ROGD should not be used to limit appropriate gender-affirming care that follows existing standards of care and clinical guidelines. The Australian Psychological Society further challenged the notion that social media or peer pressures influence a person's gender and noted that this narrative may be harmful to young people's well-being. Of note is that some authors do support additional research investigation into ROGD as a distinct clinical presentation.

Autogynephilia: A Debunked Adult Anti-Trans Theory

Another theory that propagates anti-trans stigma in its conceptualization regarding gender identity and gender identity processes is autogynephilia. In contrast to ROGD, the theory of autogynephilia has been present in the literature since the 1980s and 1990s. Ray Blanchard developed the theory of autogynephilia to offer a typology of trans women and trans feminine individuals, which he described as the identification of an erotic orientation. The term *autogynephilia* has Greek roots and can be translated to "love of oneself as a woman." Anne Lawrence suggested that autogynephilia may be conceptualized as a paraphilia and a sexual orientation, in contrast to being considered gender identity among trans women and trans feminine individuals.

Blanchard's theory suggests that there are two subtypes of trans women and trans feminine individuals: homosexual transsexuals and autogynephilic transsexuals. In her critique, Julia Serano (2010) described the definition of the homosexual transsexual subtype as a feminine gay man who medically transitions in order to attract and seduce heterosexual men. These individuals supposedly have a feminine expression from an early age and do not experience sexual arousal when dressing in clothing or fantasizing of oneself as a different gender than their assignment at birth. The second subtype is autogynephilic transsexuals that Blanchard described as a misdirected sexual variation in which men who are not gay experience sexual and erotic arousal when fantasizing of themselves as women. Some authors argue that this second subtype is a paraphilia, and this sexual motivation and fantasy is a driving force for starting medical transition.

Select Criticisms

The theory of autogynephilia has been considered by many scholars and activists/advocates as controversial, misleading, and stigmatizing. In developing the theory, Blanchard relied solely on his clinical samples. He did not empirically derive his two subtypes of trans women and trans feminine individuals but instead categorized them based on sexual orientation. The idea that trans women and trans feminine individuals can be easily divided into only two categories is an oversimplification of the diversity within this community and conflates gender and sexual orientation. It is notable that Blanchard does not seem to acknowledge that some cultures understand gender identity, gender expression, and sexual orientation as separate but related concepts. Blanchard's blatant disregard of individuals' gender identities and lived experiences as women and trans feminine individuals (by referring to them as men) is glaring. Furthermore, it is an unfounded claim to definitively state that the presence of autogynephilia is the primary underlying condition of gender dysphoria and the motivating force for medically transitioning (for those who experience autogynephilia).

This conceptualization of autogynephilia is unnecessarily pathologizing for trans women and trans feminine individuals. The focus on sexual motivations and fantasies that are described as a paraphilia has significant social, clinical, and policy implications. Distinguishing between a paraphilia versus a paraphilic disorder can be easily confused;

further, this problematic terminology and confusion can contribute to discrimination. As Serano suggested, associating trans individuals—and, indeed, trans identity—with a paraphilia can lead to common assumptions associated with paraphilias, which often include nonconsensual or criminalized sexual behavior engagement. In reality, however, trans women and trans feminine individuals are often oversexualized in today's society, as particularly evident in media depictions, and this may be a nonconsensual experience by the trans woman or trans feminine person who is the target of that oversexualization. Ultimately, this oversexualization and objectification are consistent with dominant implicit cultural dynamics that equate women's value as a person to how they can be used by others for sexual gratification, a process often referred to as sexual objectification. Sexual objectification such as this is dehumanizing and intersects with other facets of transphobic oppressions. Furthermore, suggesting that experiences of autogynephilia are a phenomenon specific to trans women and trans feminine individuals is false, as cis women have reported being sexually aroused by thoughts of themselves as women.

Finally, Serano noted that a scientific flaw in Blanchard's theory is the assumption of causality. The theory posits that the sexual motivation or impulse is misdirected, causing erotic arousal with the thought and fantasy of the self as a woman, which causes gender dysphoria and subsequently the interest and pursuit of medical transition. However, Blanchard's conclusions are based on his correlational evidence, another related anecdotal theory (e.g., erotic target location errors), and does not account for alternative reasons or effects that could explain the gendered and sexual experiences of these individuals.

A Debunked Theory?

Several papers have been published that describe conceptual flaws in the autogynephilia theory, while other studies have pointed to empirical findings that contradict the underlying central tenets of autogynephilia. The scientific discourse regarding autogynephilia has played out publicly since Blanchard's early works, with proponents and critics continuing to publish and refute each other's central assertions. However, in one succinct statement summarizing this back-and-forth discourse, Julia Serano (2010) states,

> If proponents of autogynephilia insist that every exception to the model is due to misreporting, then autogynephilia theory must be rejected on the grounds that it is unfalsifiable and therefore unscientific. If, on the other hand, we accept that these exceptions are legitimate, then it is clear that autogynephilia theory's two-subtype taxonomy does not hold true. (p. 181)

Conclusion

Anti-trans theories exist to further invalidate and delegitimize trans individuals of all ages. As efforts to increase gender literacy and trans-affirming care become more prevalent, strategies for refuting such theories will continue. However, trans and gender-diverse communities are known for their strength in challenging and dismantling systems that try to disempower and disenfranchise. Yet, institutional efforts continue to try to marginalize and oppress gender diversity by pressuring people of all ages to conform to binary gender stereotypes and attempting to block efforts to assist individuals with being their most authentic and genuine versions of themselves. Implications for these theories are far-reaching and include, but are not limited to, further stigmatizing and marginalizing trans and gender-diverse individuals, making it difficult for them to have access to basic human rights (e.g., health care, discrimination protections), and perpetuating oppression. The science upon which these theories rest has been widely critiqued by members of the scientific community as being fundamentally flawed, from sampling and recruitment limitations, to core construct measurement problems, to overall study design. By appropriately criticizing and debunking these theories, the movement toward gender affirmation and respect for all people's basic human rights can and will continue.

Archives

In the narrowest sense, archives are collections of records or historical materials that are professionally curated and maintained for the purpose of preservation and access. More broadly, the term *archives* has been used both as a theoretical concept and as a vernacular description for any collections of materials. In all senses of the term, archives have been important for Trans Studies, particularly as a resource for primary source accounts of trans lives. This entry offers a brief introduction to trans-specific archival efforts and the complexities involved in representing trans experiences in the historical record.

Although the term *transgender* was popularized in the late 20th century in North America, historical evidence shows that people have transgressed gender norms throughout human history and around the world. Thus, while the discipline of Trans Studies is only a few decades old, the practices and experiences it is based on have been ongoing for millennia. This presents several important challenges: How do we understand and interpret historical practices of gender expression that occurred prior to the emergence of the concept of "trans"? And, how do we account for different cultural contexts (both historically and currently) where there are divergent understandings of gender identity, particularly as it relates to or is conflated with sexual identity or sexual practices? To pursue these questions, archives have offered rich sites for academic exploration.

Historical materials relevant to Trans Studies can be found in a wide variety of archival contexts. Beginning in the 1980s, there have been a few independent efforts to collect trans history, such as the National Transgender Library and Archive, which began in Georgia and is now housed in the Labadie Collection at the University of Michigan, and the Trans-Gender Archive, which began at the University of Ulster in Northern Ireland and is now housed in the Transgender Archives at the University of Victoria (which is currently the largest trans archival collection in the world). There are also many LGBTQ-specific archives in North America—such as The ArQuives in Toronto, Ontario; the GLBT Historical Society in San Francisco, California; and the ONE National Gay and Lesbian Archives in Los Angeles, California—where an abundance of trans history has been collected and preserved. Finally, in more general archives, such as university special collections, historical societies, and state and federal archives, trans-related materials have often been collected inadvertently, although more institutions now devote resources to intentionally collecting in this area (e.g., Cornell University's Human Sexuality Collection, the San Francisco Public Library, and the Wellcome Library in London)

In addition to these brick-and-mortar sites, trans materials can be found in countless archival contexts online. Initiatives such as the Digital Transgender Archive, OutHistory.org, and the Queer Digital History Project support the digitization of historical materials, the development of interpretive resources, and the preservation of born-digital content. Akin to brick-and-mortar archives that inadvertently hold significant trans materials, popular online platforms—such as Facebook, Twitter, and YouTube, along with tools such as WordPress, wikis, and group forums (i.e., YahooGroups and GoogleGroups)—include such a wealth of materials relevant to trans lives, history, and community building that numerous scholars advocate that these platforms should be treated as archives as well.

Across this range of archival contexts, researchers can find many types of materials, including periodicals, newsletters, clippings, personal and organizational records, photographs, letters, diaries, clothing, academic work, brochures, and many other formats. Some of these materials represent the firsthand experiences of trans people (such as journals, letters, and photographs) and the emergence of trans identities and communities (such as newsletters and organizational records). Other materials document trans people's confrontations with the state (such as arrest records for violations of crossdressing laws), harmful encounters with non-trans people (such as police records for incidents of violence), and sensationalistic exposés of gender nonconformity (such as magazine and news coverage). This diversity of sources points to a significant tension in the archival record between materials that are *by* trans people and materials that are *about* trans people.

While archives have demonstrated increasing commitments to expand their trans holdings, what cannot be found in archives is perhaps as important as what can be found there. Generally, the experiences of more privileged factions of trans communities—such as those who are white, able-bodied, and economically advantaged—are overrepresented in archives, particularly when comparing materials created by trans people to materials created about trans people. In other words, more privileged trans communities have been able to create more materials about themselves and have also been able to find a secure, permanent archival home for those records. This inequity in archival representation has been the focus of recent efforts to capture other forms of historical memory, such as oral histories, in order to broaden and deepen trans-related holdings in archives. Yet there remains a great deal of work to be done to balance who is represented in archival holdings and how those archives are dispersed globally.

Even beyond the politics of who is represented in archives, it is critical to consider a more theoretical question: What can (and should) the archival record capture of trans experiences? After all, what is collected in archives are only fragments of lives, offering fleeting glimpses into complicated lifetimes. Particularly with respect to trans history, the challenge of accounting for bodies and embodied experiences in archival contexts presents a formidable obstacle when attempting to document trans lives. There are also instances when it is not desirable to have materials archived, especially for trans people who have carefully presented their own history and identity and for whom archives have the potential to betray them and undermine their security.

Yet despite these complexities, archives have and will continue to serve as a generative site of inquiry for Trans Studies. Archives collecting trans materials contribute to personal identity development, community formation, political activism, the enrichment of the historical record, and scholarly work that touches upon all of these areas.

Artists, Canadian

Since the concept of transness entered public consciousness in the 1950s, artists like Stormé DeLarverie and Delisa Newton have showcased their trans identity as part of their performances and, in the process, exhibited new ways to understand societal conceptualizations of gender and sex. Trans artists today remain on the forefront of creating groundbreaking work that pushes gender and sexual binaries. Particularly innovative has been the work of BIPOC (Black, Indigenous, and People of Color) trans artists, who take an intersectional approach to fight white supremacy and transphobia in tandem. Because the experiences of white trans artists are prioritized in scholarship on artists, just as white people are at the forefront of trans studies scholarship more generally, this entry focuses on the work of BIPOC Canadian artists as an intervention in these traditional whitening practices. The artists covered are Ravyn Ariah Wngz, Rosina Kazi, Kyisha Williams, Tobaron Waxman, Aiyyana Maracle, and Raven Davis.

Ravyn Ariah Wngz

Ravyn Ariah Wngz, also known as the Black Widow of Burlesque, is an Afro-Indigenous trans woman based in Tkaronto/Toronto. She cofounded ILL NANA/DiverseCity Dance Company, a queer multiracial dance company, and her career as a choreographer and dancer has spanned two decades. Her work has largely focused on breaking down the barriers of transphobia, ableism, and sizeism in dance that shut people out of experiencing and moving in their bodies. Wngz confronts head-on the anti-Blackness inherent in dance and much of the arts, weaving Black liberatory struggles into her content and choreography. Her work combines traditional ballet practice, street styles, and vogue, bringing an activist aesthetic into all that she does. Wngz's activism has resonated globally, with a speech she gave following protests against racist monuments in Tkaronto garnering over three million views as of August 2020. Her artistic performance and activist practices have galvanized people around ideas of justice, liberation, and freedom.

Rosina Kazi

Similarly, nonbinary artist Rosina Kazi's work has acted as a provocation for discussions of environmental justice, white supremacy, and transphobia for the past three decades. Their music, both as a solo artist and as part of the Tkaronto-based electronic duo LAL, speaks to structural and systemic violence and the power of activists fighting for change. For example, their song "Self Defense" speaks to the ongoing surveillance and violence facing racialized people in Turtle Island (i.e., North America) and Inuit Nunangat, the homeland of the Inuit in Canada. It describes a world where racialized artists and activists are not safe from a state that seeks to stop their revolutionary creative practices.

Kyisha Williams

Black, nonbinary filmmaker and actor Kyisha Williams creates short narrative and documentary projects on socially relevant issues. They take what can be considered "heavy" topics (such as incarceration, sexuality, and assault) and make them accessible and easier to discuss by crafting character-driven, engaging stories. In other words, Williams takes "hard to look at" issues and makes them beautiful.

They use film, as it provides an opportunity to work collaboratively and to take part in healing our society by engaging audiences in vital dialogue about how we live or could live. A critical part of Williams's work is discussing the nuances of trans experiences and the need to address the criminalization of trans women of color.

Tobaron Waxman

Tobaron Waxman is a curator, visual artist, and trained vocalist in Jewish liturgical music who combines these skills to create site-specific installations. Waxman, a former Orthodox Jew as well as trans, often uses traditional Jewish religious motifs to shed new light on issues of identity, gender, religion, and politics. For example, in the 2006 piece *Amidah Triptych,* Waxman inserts a nude trans man into scenes of men reciting the Jewish prayer, reflecting that trans men belong in this setting, but, as symbolized by the man's nakedness, they remain vulnerable to scrutiny and expulsion. Waxman was the first trans artist to be exhibited in a major Jewish museum.

Aiyyana Maracle

The late Indigenous (Haudenosaunee) artist Aiyyana Maracle was a performance and video artist, storyteller, and theater director whose work called attention to precolonial Indigenous cultural traditions that recognized more than two genders. Maracle's work sought not only to decolonize gender but also to forefront the voices of Indigenous trans women like herself, who have been erased from history and are still largely ignored today. Her one-person show, *Chronicle of a Transformed Woman,* which she subsequently published as a book, detailed her use of traditional medicine rituals during her transition process and her struggles against colonization.

Raven Davis

Two-spirit (Anishinaabe) visual artist Raven Davis, who works between Toronto and Halifax, uses performance, photography, installation art, and other mixed-media methods to advocate for disability justice and address ongoing colonialism and violence toward Indigenous people. They root their work firmly in disability arts practices, which draw on disability theory and disability justice organizing and bring together Deaf, Mad, sick, and disabled artists. Davis's work also directly calls out the Canadian government for its role in the violence faced by Indigenous people. From jingle-dress dancing on a bloody Canadian flag to producing large-scale photographs that mock Parks Canada 150 advertisements by inviting tourists to visit reservations, Davis challenges white supremacy, colonial violence, and systemic transphobia.

Artists, U.S.

Growing up in a cisnormative society characterized by an entrenched gender binary, trans people have had to invent and create a space for themselves. It is thus not surprising that many trans people have been artists and have developed groundbreaking work in various media. Through their artistic contributions, they have helped establish an identity

and a discursive place for themselves and the larger trans community. Moreover, given that trans artists challenge societal assumptions about gender, it is likewise not surprising that many also do not conform to the expectation that they limit themselves to one artistic genre; instead, they tend to produce work in a variety of disciplines and/or mix different media. This entry discusses six contemporary U.S. artists who have received widespread critical acclaim: micha cárdenas, Zackary Drucker, Juliana Huxtable, Amos Mac, Wu Tsang, and Alok Vaid-Menon. These artists express themselves through numerous creative forms, including performance, film, digital media, photography, self-portraiture, fashion design, poetry, and prose.

micha cárdenas

A first-generation Colombian American, micha cárdenas is a trans female educator, writer, digital media artist, and clothing designer. She is an assistant professor of Art and Design: Games + Playable Media at the University of California–Santa Cruz, and coauthor of the books *The Transreal: Political Aesthetics of Crossing Realities* (2012) and *Trans Desire/Affective Cyborgs* (2010).

Her artistic work supports the health and welfare of people, especially trans women of color, and the planet using interactive media design, virtual reality, science fiction, and performance. In 2015, cárdenas created the online, interactive game *Redshift and Portalmetal,* which focuses on a trans woman of color who must travel to other worlds because her planet's environment is becoming unlivable. In describing the work on her website, cárdenas states that the game poses the question, "As climate change forces us to travel to the stars and build new homes and families, how do we build on this land, where we are settlers, while working to undo colonization?"

In 2020, cárdenas created *Sin Sol* (*No Sun*), an augmented reality game that tells the story of climate-induced wildfires through the eyes of a trans Latinx artificial intelligence hologram. Set 50 years in the future, the game depicts the environmental collapse occurring now using three-dimensional scans of forests from the Pacific Northwest. Like *Redshift and Portalmetal, Sin Sol* considers how climate change intersects with race, gender, and immigration, as well as the interplay between personal trauma and environmental trauma.

cárdenas's projects are not limited to virtual reality and future worlds; through her art, she also seeks to have a direct impact on the lives of marginalized peoples today. For example, she has collaborated on *UNSTOPPABLE,* an effort to design and disseminate information about how Black communities can produce DIY bulletproof clothing to address the horrific rate of murders of Black people, particularly Black trans women. She also initiated the development of *Local Autonomy Networks (Autonets)*, online and offline community networks that exist outside of corporate-owned infrastructures, including a line of mesh-networked electronic clothing that can alert other nearby Autonet garment wearers that someone needs help and their location. The project aims to increase community autonomy and reduce violence against people because of their race, gender, and sexuality.

Zackary Drucker

Zackary Drucker is a white trans female photographer, actor, and film and television producer whose work documents her own and other trans people's experiences. For example, she had a 6-year relationship with trans male film producer and director Rhys Ernst, which they recounted through photographs that they exhibited as "Relationship" at the Whitney Museum of American Art in 2014. The photos chronicle the development of their relationship and their different gender transitions and capture everyday moments in their lives, like trips together and relaxing at home, which serve to humanize and valorize the relationships of trans people. "Relationship" was released as a book in 2016.

Drucker and Ernst have also collaborated on other projects. They created the short film *She Gone Rogue* (2012), in which Drucker plays a fictional character who has dreamlike encounters with the groundbreaking trans women performers Flawless Sabrina, Vaginal Davis, and Holly Woodlawn. The film is both an homage to the artists, who were role models for Drucker, and a representation of Drucker's need to "go rogue" and forge her own gender path. Drucker and Ernst also worked together from 2014 to 2017 as consultants and producers on the Amazon series *Transparent,* where they sought to ensure that trans people were portrayed accurately, and on *This Is Me* (2015), a series of 5- to 6-minute documentaries about issues

faced by trans people today based on topics raised in *Transparent*. Drucker is featured in an episode on trans women sisterhood.

A central theme of Drucker's artistic work is the need for trans people to take control of how they are represented. This concern is also evident in her support of other trans artists. In 2017, she edited a special issue of *Aperture* magazine on "Future Gender," which focused on how trans people from different countries have used photography to illustrate their own lives, communities, and histories.

Juliana Huxtable

A Black trans female visual artist, writer, performer, model, and DJ, Juliana Huxtable explores the intersections of race, gender, and sexuality in her art using a variety of media, including self-portraiture, text-based prints, writing, and music. Among her best-known works are photographic images in which she places herself within historical and Afrofuturistic settings, signaling that Black trans people have and will continue to exist. For example, in *History (Period Piece)* (2013), Huxtable superimposed an image of herself with U.S. and British flags in her hair against a tapestry depicting merchant ships from the era of colonization and the slave trade. The piece simultaneously addresses how this history informs conceptions of Blackness, transness, and queerness today and how Huxtable herself must contend with this past.

Two of her other visual works, *Nuwaubian Princess* (2013) and *Untitled in the Rage* (Nibiru Cataclysm; 2015), are nude self-portraits that have an ethereal quality, as if to suggest a vision of a world in which the bodies of Black trans women can be centered and respected. In *Untitled in the Rage,* Huxtable, whose skin is painted turquoise green and her long braids highlighted in neon yellow, is sitting on her heels and positioned in profile, so that her body draws in the viewer. But while the image invites one's gaze, its representation of a trans woman of color challenges stereotypical ideas and ideals of race, gender, and sexuality. At the same time, the supernatural and fantastical elements of the piece, along with the reference to the Nibiru Cataclysm (a supposed impending disastrous encounter between the Earth and another planetary object), point to the existence of different realities and the fluidity of identities.

Huxtable has also created works that address her experiences growing up, her interest in science fiction and online spaces, and how race, gender, and sexuality are conceptualized in the digital age. In the series *Seven Archetypes* (2012–2013), she contextualized her gender transition alongside dominant constructions of gender and sexuality. In *Untitled (For Stewart;* 2012), Huxtable created a color inkjet print of one of her all-caps, stream-of-consciousness poems that describes the misogyny of video games, the blurred lines between video games and pornography, her alienation from boys, and her vision of herself as female. This poem was featured in her poetry book, *Mucus in My Pineal Gland* (2017). She also cowrote, with artist Hannah Black, the science fiction novella *Life;* it is a narrative about two risk analysts taking on the ultimate catastrophic assessment: an impending apocalypse.

Amos Mac

A white trans male photographer, editor, and writer, Amos Mac has greatly increased the visibility of trans people through a variety of media. In 2009 he cofounded, with Rocco Kayiatos, *Original Plumbing,* the first U.S. print magazine focused on trans male culture, and served as its editor for the 20 issues that were published over the next decade. The magazine's photographs (many taken by Mac) and stories helped many trans men to see images of people like themselves, and its coverage of topics like developing careers and becoming fathers addressed issues that were not being discussed anywhere else at the time. Highlights of the magazine were reprinted in a book, *Original Plumbing: The Best of Ten Years of Trans Male Culture,* in 2019.

In addition to his photography for *Original Plumbing,* Mac's pictures have been featured in dozens of publications, including the *New York Times, Interview,* and *Out.* In 2011, he published his photographs of Zackary Drucker in *Translady Fanzine* and the exhibition "Distance Is Where the Heart Is, Home Is Where You Hang Your Heart." Mac also contributed to Drucker's "Future Gender" issue of *Aperture* magazine with photographs of Juliana Huxtable. In 2015, he broke new ground by photographing that fall's collection of the H&M fashion brand "& Other Stories," which was the first such photo shoot to use all trans models and crew members.

In recent years, Mac has written for television and film. He was the associate producer for the documentary series *Gaycation* (2016–2017), which explored LGBTQ cultures around the world, and is currently a story editor for the relaunch of the teen drama series *Gossip Girl* (2021). With film director Aisling Chin-Yee, Mac cowrote *No Ordinary Man* (2020), a documentary feature about trans male jazz musician Billy Tipton.

Wu Tsang

Born to a Chinese father and a Swedish American mother and identifying as gender fluid, filmmaker, visual artist, and performer Wu Tsang has described herself as being in a place of "in-betweenness." This sense of existing outside of traditional categories is similarly reflected in her work, which often dismantles the boundaries between fiction and documentary, performance and realism, and public and private spaces. A case in point is Tsang's first feature film, *Wildness* (2012), which centers on the Silver Platter, a Los Angeles bar that catered to LGBTQ Latinx immigrants.

Wildness, which premiered at the Museum of Modern Art, developed out of a weekly performance art party of the same name that Tsang co-organized at the Silver Platter from 2008 until the bar closed in 2010. The film depicts how the parties led to the mixing of the bar's long-time patrons with young artists and performers and how the two groups at times had to address differences in race, gender, class, and culture. A central question of *Wildness* involves the development of safe spaces: What does it mean to different communities, and when two communities are marginalized, whose safety takes precedence? While the film takes a narrative approach, it also has elements of magical realism, with the bar itself serving as one of these narrators. Through this technique, Tsang shows that environments are multifaceted and dynamic—as much actor as acted upon.

Another of Tsang's films, *Duilian* (2016), likewise blurs the line between imagination and reality. It envisions the intimate relationship thought to have existed between Qui Jin, a turn-of-the-20th-century Chinese poet and revolutionary, and Wu Zhiying, a calligrapher with whom Jin frequently collaborated. In the film, Tsang plays Zhiying, and boychild, a gender-nonconforming performance artist with whom Tsang has often collaborated, plays Jin. Scenes of the two of them conversing in Jin's poems are interspersed with sequences of wushu martial arts and documentary-style footage of boychild in 19th-century clothing walking through the streets of contemporary Hong Kong. Although fictive, *Duilian* serves to write the couple into history, which is especially important given the erasure of their relationship then and often still today.

Alok Vaid-Menon

Alok, as they are known professionally, is a nonbinary trans femme Indian American performance artist, writer, and fashion designer. They first gained critical acclaim as part of the spoken word duo DarkMatter with Janani Balasubramanian from 2013 to 2017. The group's name and poetry called attention to the invisibility of queer and trans people of color, and their performances highlighted how predominantly white queer and trans communities, like the larger white society, often marginalize people of color and fail to examine their racial privilege.

Alok's physical appearance (which often mixes traditionally male and female gender expressions) and artistic work challenge the gender binary and what constitutes "female" and "male" aspects of presentation. They are the author of *Femme in Public* (2017) and *Beyond the Gender Binary* (2020); the latter is a book aimed at teens and young adults in which Alok uses some of their experiences as a gender-nonconforming individual to point out how society tries to limit gender expression when the only actual boundaries are people's imaginations.

Alok's fashions are also designed to confront gender binaries, as well as transmisogyny, femmephobia, and racism. In 2019, they released *Natural Bodies,* their third fashion collection, which took pieces and elements of clothing that are stereotyped as for women and "feminine" (e.g., skirts, gowns, frills, bright colors) and questioned why these aspects of dress are gendered and not readily available to people of all genders. At the same time, Alok linked the dismissal of femme fashion as superficial and inauthentic to the denial that trans women are "really" women by naming each design after a word that is used to reject the authenticity of trans identities, such as "biological" and

"innate." Alok's collection speaks to the genuineness of the lives of femmes, particularly trans femmes of color, and forces the viewer to recognize how cisness, masculinity, and whiteness are commonly treated as "natural."

Asian American People

Asian Americans constitute a small but growing segment of the trans community. Trans Asian Americans face marginalization both within the transgender community and within the Asian American community. The trans Asian American population is exceptionally diverse.

Marginalization and Diversity

Just as trans Asians and Pacific Islanders (APIs) face marginalization within heteronormative API communities, so trans APIs can face marginalization in the white-dominant LGBTQIA+ community; to understand trans APIs, one must understand their position in both spheres.

The trans community in the United States—like the Asian American community—is characterized by great demographic diversity as well as diversity in terms of gender identity and expression. The trans community obviously includes individuals of every racial and ethnic background, including African Americans, Latinos and Latinas (Latinx has recently become popular as a gender-neutral term to describe them), Asian Americans and Native Americans, and white people of every European national origin. The diversity of the trans community in terms of gender encompasses people who pursue medical interventions, those who do not, those who identify as men or women, those who identify as genderqueer or nonbinary, those who crossdress part of the time, those who do some form of performative drag as entertainment, those who undergo a purely social transition, and of course those who are assigned male sex at birth and those who are assigned female sex at birth as well as those who are intersexed but nonetheless assigned male or female at birth.

Likewise, the Asian American community includes the full spectrum of gender identity and expression as well as a wide variety of national origins and ethnicities. The term *Asian American*, like the term *trans,* is both a social construction and a term of relatively recent origin. Until the mid-20th century, the now-derided term *Oriental* was in common usage throughout the United States and the English-speaking world but has since been rejected because of its Orientalist baggage and the pejorative connotations associated with it. But, just as the term *Asian American* gained favor in the 1970s and 1980s, so in the late 1990s, other terms came to the fore, such as Asian/Pacific Islander and Asian Pacific American (APA). Of course, all terms of self-identification and group identification are social constructions, and all have a relatively arbitrary relationship to the individuals and groups they designate, but some terms are more accurately descriptive, empowering, and/or inclusive than others, and so it is with both trans and Asian American.

Consider the terms that preceded both trans and Asian American. In the case of trans or transgender, these terms came into increasingly common usage

from the 1970s onward to unite disparate groups who otherwise might be referred to as transsexuals, transvestites (or crossdressers), and drag queens, to mention a few terms commonly used up until that point. Similarly, before the adoption of the term *Asian American,* those who now identify as such had available to them only either *Oriental* or nationality-specific terms such as *Chinese, Indian, Filipino,* or subnational terms of identification. Thus, both with the trans community and with the Asian American community, the use of these more empowering terms enabled members of those communities to identify with broader formations and organize politically across different categories.

To understand trans APAs requires that we know something of the Asia/Pacific region to which they trace their origin or ancestry, for the APA communities in the United States have been shaped by the history of Asia and the Pacific even as they evolve within the context of U.S. history and American society. And in fact, Asia is by far the world's largest continent by area and holds 59.54% of the world's population; East Asia (21.53%) and South Asia (24.89%) each account for a quarter of the world's population. Asia has between 24 and 52 countries, depending on how one defines a national state and whether one includes Middle Eastern countries contiguous with the Asian continent. The Pacific is the world's largest ocean, and Oceania is vast in size but holds just 0.55% of the world's population scattered across tens of thousands of islands. Taken together, the Asia/Pacific region encompasses a wider array of ethnicities, cultures, languages, dialect, and religions than any other.

It is ironic that APAs are routinely referred to as a "minority" group in the United States, given that Asians constitute nearly 60% of the world's total population, but Americans of Asian and Pacific origin are just 6.1% of all Americans, boosted by the increasingly large waves of immigration from Asia since Congress enacted the Immigration Reform Act in 1965. In fact, APAs are the fastest growing demographic group in the United States and "Asian America" encompasses people of scores of different national origins, hundreds of subnational communities of origin, and thousands of ethnolinguistic groups from across the Asia/Pacific region. Hence, to speak of "trans APIs," one must speak of a complex intersection of trans and Asian America.

Furthermore, it is important to understand that there is no single Asian understanding of trans or gender variance but rather thousands of different understandings (or misunderstandings). It is therefore difficult to make any generalizations about trans acceptance in the Asia/Pacific region. However, it is certainly true that in no country in contemporary Asia and the Pacific today is there full trans acceptance, whether in the relatively tolerant Buddhist-majority Thailand and the somewhat tolerant Roman Catholic–majority Philippines or the relatively hostile People's Republic of China (PRC) or the Kingdom of Saudi Arabia, which long ago adopted the extreme form of fundamentalist Wahhabi Islam.

Traditions and Identities in Premodern Asian and Pacific Islander Societies

In every premodern Asian and Pacific Islander society, there is some form of "third sex/third gender subject position," to use anthropologist Gilbert Herdt's term.

Korea alone has at least four distinct traditions that anticipate contemporary LGBTQIA+ identities. First, there was the *hwarang* warrior elite—sometimes referred to as the "flower boys of Silla"—an elite corps of archers who dressed in long flowing gowns and wore makeup. Second, there were the *namsadang,* the troupes of actors who went from village to village. Among the *namsadang*, the youth played women's roles, as in Elizabethan English theater. It is said that the youth were often lovers of the older men in the corps. Third, there was the tradition of "boy-wives," in which youth would wed older men for a period of time. And finally, there is the *paksu mudang*—the male shaman who performed what was a woman's role in the ancient shamanic spiritual tradition indigenous to Korea. To speak of "trans APIs" before the late 20th century therefore is to engage in anachronism; it would be more accurate to speak of the proto-transgenderal—those who resemble contemporary trans people in some respects while differing from them in others, yet still anticipating contemporary trans identity or identities.

An example of the proto-transgenderal can be found on the Indonesian island of Sulawesi, where feminine males carry on the *bissu* tradition, while

in India, the ancient tradition of the *hijra* continues to the present day. Vietnam also has a shamanic tradition, known as *dao mau*. The Pacific Islands have many homoerotic and proto-transgenderal traditions, including those of the *māhū* in Hawai'i, the *fa'afafine* in Samoa, the *fakaleiti* in Tonga, the *vaka sa lewa lewa* in Fiji, the *rae rae* in Tahiti, the *fafafine* in Niue, and the *akava'ine* in the Cook Islands. And of course, there are the traditions of theatrical crossdressing such as the Beijing opera *dan* in China and the kabuki *onnagata* in Japan.

Various identity formations and practices that anticipate contemporary trans identities exist in every premodern Asian and Pacific Islander society whether contemporary Asians and Americans are aware of them or not; any assessment of the intersection of trans and API/APA should at least acknowledge this hidden history. This history is relevant to an understanding of the challenges facing those at the interstices of trans and API/APA insofar as all too many APAs and APIs have internalized more modern (mis)understandings of trans and gender variance as being foreign to their countries and cultures of origin, when in fact the opposite is true.

Immigration and Inclusion

Although APIs have lived in what is now the United States since the mid-19th century, it was only with the great waves of Asian immigration in that century that APIs attained visibility in American society, which produced a hostile and at times violent reaction. The needs of trans APIs today reflect aspects of that history that continue to the present day, including the financial precarity of so many APA immigrants. Those who are gender variant in some way labor under multiple oppressions of gender identity and expression as well as race, ethnicity, national origin, and citizenship status. While trans API immigrants are as much in need of services for immigrants as cis APIs, they may be reluctant to go to organizations and social service providers serving immigrant communities for fear of discrimination and further marginalization. Those trans APIs who are undocumented face all the formidable challenges of other undocumented immigrants as well as discrimination and marginalization based on their gender identity or expression. Unfortunately, organizations and institutions serving the white-dominant mainstream LGBTQIA+ community may be indifferent to the special needs and complex challenges of trans APIs, especially migrants.

U.S.-born English-speaking trans APIs may not face the challenges that API immigrants do but may still face discrimination and marginalization within the LGBTQIA+ community as well as in mainstream American society. They may also face the exoticization and fetishization of API identities that are unfortunately still prevalent in the United States today. And trans APIs, regardless of English-language proficiency and regardless of how long they have lived in the United States, may face the same challenges as other people of color with regard to police harassment and maltreatment in the criminal justice system as well as the health care system and in the provision of social services.

It is impossible to estimate the population of trans APAs because the U.S. Census does not include questions about sexual orientation or gender identity. While it is true that some LGBTQ organizations have extrapolated estimates of LGBTQIA+ Americans from census figures documenting the number of households in which two adults of the same sex (assigned at birth) are living together, that extrapolation—questionable even with all-white households—becomes even more so in the case of Asian households, given the "homosociality" of Asian and Pacific Islander societies. Indeed, extrapolating the number of trans APAs is simply impossible using the census as it is currently constituted.

About the only generalization that one can make about trans APAs and APIs is that they face the same patriarchal oppression and trans(gender) phobia as white trans people with the added multiple oppressions of race, ethnicity, national origin, and immigration and citizenship status. At the same time, trans APIs and APAs are increasingly visible in American society and in the Asia/Pacific region; this visibility, in turn, highlights their notable diversity.

Asylum

Asylum is a form of legal relief and protection to migrants who are fleeing persecution in their countries of origin. For many trans migrants, asylum is often the only option to apply for legal status in the United States, given the family reunification and social class biases of the U.S. immigration system. The two most common ways to apply for legal permanent residency are through direct family ties or through sponsorship by an employer. Many trans people experience family rejection and cannot access legal status through family reunification. Additionally, trans people face many barriers to education and employment and often do not have access to the cultural, class, and economic capital required for labor migration to the United States, which privileges highly educated professional workers. To apply for asylum, trans migrants must be able to prove that they experienced persecution on the basis of their gender identity and be able to navigate numerous social and legal barriers to asylum. Trans studies scholars have theorized asylum for trans migrants in order to understand how legal processes are shaped by essentialist constructions of sexuality, gender, and race, as well as how ideologies of normative sex and gender inform ideals of citizenship and national belonging.

Applying for Asylum

The 1951 United Nations (UN) Convention Relating to the Status of Refugees and the 1967 Protocol Relating to the Status of Refugees form the foundation of international law governing the rights of refugees and asylum seekers. The United States signed the UN Convention and the Protocol in 1969, and in 1980, the U.S. Congress passed the Refugee Act, which adopted the human rights standards laid out by the UN and established a system for the admission of refugees and asylum seekers in the United States. The 1980 Refugee Act codified the UN definition of a refugee as someone who is fleeing persecution or who has a "well-founded fear" of persecution "on account" of race, religion, nationality, political opinion, or membership in a particular social group. The persecution must be committed by the government or by individuals or groups that the government refuses to or cannot control, and applicants must show a nexus between the persecution they experienced and the grounds on which they are applying for asylum. All asylees have to fit this definition of refugee but are subject to different bureaucratic procedures. To apply for asylum, an individual must enter the United States and then apply, unlike refugee applications, which are processed abroad.

There are two ways to apply for asylum in the United States: affirmatively and defensively. Affirmative applications are from individuals who are currently in the United States and decide to apply for asylum before they are put into removal proceedings by the government. These applicants submit an application and then receive a nonadversarial interview with an asylum officer. Defensive asylum applications are from individuals who have already been put into deportation proceedings and are arguing for an asylum claim as a defense. Noncitizens whose affirmative applications are denied and who are not in lawful status are also placed in removal proceedings. Once in removal proceedings, noncitizens are subject to mandatory detention while their asylum cases proceed, which may take months or years. Defensive applications

go directly to immigration court, where the applicant must argue for their case in front of an immigration judge and in the presence of an attorney from U.S. Immigration and Customs Enforcement (ICE) who will argue for the deportation of the applicant. The main purpose of the asylum interview and immigration court hearing is to establish the applicant's credibility and their eligibility for legal relief, which can take the form of a grant of asylum, withholding or removal, or protection under the Convention Against Torture (CAT). The latter two forms of relief can only be granted by an immigration judge, not an asylum officer.

Trans Asylum Applicants

Asylum adjudicators and immigration courts began to recognize gender and sexuality as grounds for asylum in the late 1980s and early 1990s, through cases dealing with women fleeing domestic violence as well as with lesbian and gay applicants. These cases opened the category of "membership in a particular social group" to sexuality- and gender-based asylum claims, which set a legal precedent for trans asylum seekers. In 1994, Attorney General Janet Reno issued a memo establishing that gay men and lesbians constituted a particular social group, and in 2000, the Ninth Circuit Court of Appeals decided *Geovanni Hernandez-Montiel v. INS,* which became the first published case involving a trans asylum applicant. Geovanni Hernandez-Montiel, a teenaged migrant from Mexico, was granted asylum not as a transgender woman but as a "gay man with a female sexual identity," demonstrating how trans asylum applicants in the late 1990s had to use creative legal strategies and draw on established legal categories of gender and sexuality to build their cases and be legible to asylum adjudicators. This formulation of "gay man with a female sexual identity" was the established legal precedent available for trans asylum applicants until 2007, when the Ninth Circuit Court decided *Nancy Arabillas Morales v. Alberto Gonzales* and used the language of "male-to-female transsexual" and female pronouns to refer to Morales, implicitly recognizing "transsexuals" as a particular social group.

Since 2007, there have been several more published circuit court decisions that recognize "transgender" and "transsexual" as particular social groups. However, even though there was a lack of published cases during the early 2000s that used the category of transgender, immigration attorneys in the United States were able to obtain grants of asylum for clients in affirmative asylum proceedings, which were not published and therefore could not be established as precedent. The adoption of transgender as an established legal category in precedential asylum law was in part a consequence of the increased circulation of the language of "transgender" in national and international human rights discourses and by the advocacy efforts of immigrant rights organizations. For example, U.S. Citizenship and Immigration Services worked with the national LGBTQ immigrant rights organization Immigration Equality for 2 years to develop a training module for asylum officers to learn how to better adjudicate asylum claims by LGBTI persons. Released in 2012, the module, "Guidance for Adjudicating Lesbian, Gay, Bisexual, Transgender, and Intersex (LGBTI) Refugee and Asylum Claims," provides recommendations on how asylum officers should consider trans asylum applicants in relation to the "particular social group" category.

Even though legal precedent has established that persecution on the basis of one's trans identity constitutes grounds for an asylum claim, many social and legal barriers exist for trans migrants applying for asylum. Social class and gender not only shape the ability of trans people to migrate to the United States to file an asylum claim but also constrain access to an immigration attorney, whose services are necessary to help the applicant navigate the complicated legal system and develop the strongest possible case, which may include country condition reports, expert witnesses, and other forms of evidence. Although national LGBTQ immigration organizations such as Immigration Equality, the National Center for Lesbian Rights, the National Center for Immigrant Justice, and the Transgender Law Center have asylum programs and provide pro bono legal support for many trans asylum seekers, many trans migrants might not be aware of these resources. Furthermore, the increasing criminalization of immigration since the 1990s has created more legal barriers that disproportionately affect trans asylum applicants. For example, the Illegal Immigration Reform and Immigrant Responsibility Act of 1996 implemented a 1-year filing deadline for asylum, expedited removal laws,

and enacted mandatory detention. The REAL ID Act of 2005 also increased the burden of proof on applicants for asylum and withholding of removal claims, requires applicants to corroborate their claims with additional evidence, and makes it easier for an asylum adjudicator to determine that the applicant lacks credibility.

Theorizing Asylum

Scholars have examined asylum cases and the history of asylum for trans migrants in order to understand how legal processes are informed by social constructions of gender and sexuality. Asylum decisions are framed as legal matters of fact, yet asylum is actually a form of discretionary relief, not a right to be automatically granted by an asylum officer or immigration judge. The unevenness of asylum grant rates across adjudicators and regions illustrates how decisions can be informed by the transphobia, homophobia, or racism of the asylum officer and immigration judge. Some scholars have focused on how the immutability standard in asylum law, which requires trans applicants to demonstrate a nexus between their trans identities and the persecution they have experienced, produces legal definitions of gender and sexuality as biological and innate. Trans asylum applicants have to present their gender and sexual identities as essential and fixed, even though the basis of their asylum claims rest on the argument that they have experienced persecution as a result of shifting gender identity and presentation. Applicants need to show that they are recognizable as trans or gender nonconforming in both their written statements and through their bodies when they appear before an asylum officer or immigration judge. In this way, trans asylum provides a vantage point for examining how gendered and sexualized subjects are made legible to legal institutions as being worthy of protection.

Trans asylum also functions as a site for understanding citizenship and national belonging as structures undergirded by racialized ideologies of sex and gender. Scholars have explored this in several ways. First, they have analyzed how the asylum process tends to reproduce the exclusions that structure the regular immigration system. Historically, asylum law has been interpreted in ways that presume a male subject fleeing an oppressive regime. Starting in the late 1980s, courts began to expand interpretations of asylum law to include gender- and sexuality-based claims, yet the asylum process still privileges applicants who are male, are heterosexual, have higher socioeconomic status, and are from particular countries. This is due to the ways that asylum determinations are often shaped by U.S. foreign policy concerns and the ways that gender, race, and class shape a migrant's ability to obtain a successful grant of asylum. Second, scholars have investigated how the asylum process requires trans migrants to provide very detailed accounts of violence they have experienced and to show that their countries of origin are unsafe places for trans individuals as a larger group. Trans and queer migration studies scholars argue that this requirement of demonstrating systemic persecution illustrates how the asylum process reproduces dominant forms of racism and imperialism through the attribution of homophobia and transphobia to other cultures and other nation-states. Asylum applicants must represent their countries of origin as violent and oppressive places for trans people, in contrast to the United States, which, as the country granting asylum, is positioned as a democratic and safe space for trans migrants. This construction obscures the ways that the U.S. asylum process itself subjects trans migrants to inhuman treatment and physical and sexual violence in immigration detention centers. The construction of the United States as a welcoming space for trans migrants also contrasts with the discrimination and forms of structural inequality that trans communities within the United States disproportionately experience.

Athletes, College Sports

Because sports teams have historically been separated based on a binary understanding of sex, the question of which team a trans athlete can play on has challenged sports organizations (1) to develop policies that enable trans students to participate according to their gender identity and (2) to address how biologically based sex differences might affect their participation on sex-segregated teams. This question is particularly salient for trans women seeking to join women's teams. Trans female athletes often face opposition, as well as an assortment of eligibility rules, depending on the steps they have taken as part of their transition, as well as where they live and their level of play. But both trans women and trans men are becoming more visible in collegiate athletics, which is helping to change an aspect of college life in which transphobia often remains rampant.

Policies for Trans Student Athletes

Policies for trans student athletes vary according to level of play. These policies focus on binary trans people and, as of 2020, very few specifically included nonbinary trans identities.

NCAA Policy Recommendations

The National Collegiate Athletic Association (NCAA) governs intercollegiate athletics for more than 1,200 member institutions. The NCAA began thinking about how to include trans athletes in college sports in 2009, when it convened its first meeting to discuss the topic. In 2011, the NCAA released a trans policy recommendation, which member institutions could either adopt or develop a different policy that met with the NCAA's approval. At the same time, it issued the "NCAA Inclusion of Transgender Student-Athletes" resource guide to help colleges ensure that trans athletes received fair, respectful, and legal access to sports teams. The guide included recommendations for best practices related to facilities use, inclusive language, dress codes and uniforms, and the education of athletics staff and athletes.

The NCAA policy recommended when and on what team trans athletes could compete, based on the level of testosterone in their bodies as indicated by testing. Trans men who are medically transitioning commonly take testosterone, but it is considered a banned substance in sports because of its performance-enhancing effects. As a result, trans male athletes need to receive a medical exception to begin taking testosterone. Once these athletes start on testosterone, they can immediately play on a men's team but are no longer eligible to compete on a women's team. Trans male athletes who socially transition, which may include changing their name, pronouns, and/or appearance but who do not take testosterone, may continue to compete on a women's team.

In contrast, trans female athletes must complete 1 calendar year of testosterone suppression treatment before they can join a women's team. In the interim, they can continue to compete on a men's team, even if they socially transition. The purpose of requiring trans women to undergo this treatment prior to participating on women's teams is to try to maintain competitive equity among cis and trans women. However, some trans advocates believe

that the policy is discriminatory and unethical because it forces trans women to medically transition when they may not want or be ready to do so.

The NCAA policy recommendation has enabled many trans athletes to participate in college sports according to their gender identity. In 2005, Keelin Godsey, a track and field athlete for Bates College, became the first known trans athlete in the NCAA when he socially transitioned and continued to compete on the women's team and subsequently in two women's Olympic trials. In 2010, Kye Allums, a basketball player for the George Washington University women's team, came out as a trans man and became the first openly trans NCAA Division 1 athlete. Since the implementation of the NCAA recommendation, hundreds of trans athletes have participated across all sports without issue. Although trans men have had an easier time participating, some trans women also have competed. In 2019, Franklin Pierce College runner CeCé Telfer became the first openly trans collegiate champion when she won the Division II championship in the 400-meter hurdles. Telfer's success, however, sparked a national debate about the inclusion of trans athletes.

Intramural Sports

The National Intramural-Recreational Sports Association (NIRSA), which governs collegiate recreational sports that participate in the NIRSA championship series, implemented a trans-inclusive policy in 2015. The policy allows trans athletes to compete in intramural sports and sports clubs based on their gender identity, without restriction. Colleges with intramural teams that are not involved in NIRSA events can develop their own policies for the participation of trans intramural athletes. These policies have largely supported trans students in competing according to how they identify their gender.

Opposition to Trans Athletic Participation

Trans women are often the focus of harsh criticism for wanting to participate in sport, while trans men frequently receive less attention and do not experience a similar level of pushback, even if they stay on a women's team and are successful in their sport. Additionally, the participation of trans women on women's sports teams has become a political flashpoint that threatens the ability of athletics leaders to adopt sound policies that enable trans athletes to participate according to their gender identity.

The scientific understanding on which the NCAA recommendation is based is evolving. Currently, there are few studies of trans athletes and the impact of hormones on transitioning bodies. As more research considers the effects of hormone treatments on athletic performance, collegiate policies must be able to change to reflect new knowledge.

Additionally, policies for collegiate athletics may be challenged by state laws that require student athletes to compete as the sex they were assigned at birth. In 2020, Idaho passed such a law, banning trans women from participating on women's teams at the youth, high school, and collegiate levels. Because this law is contrary to the NCAA recommendation, colleges in the state will be forced to decide which to violate, if the law is not overturned in the courts. The outcome will have tremendous repercussions for trans athletes.

The challenge for all institutions and the NCAA is to determine how best to encourage the participation of trans athletes in college sports while being limited by a model of athletic competition that is based on sex segregation.

Athletes, Pro Sports

Since Renée Richards's successful quest to compete in events sponsored by the Women's Tennis Association (WTA) in 1977, the circumstances under which trans people have the right to compete in professional (and elite amateur) sports has been a point of contention within sport associations, scholarly research, and wider public discourse. Individual trans athletes have been catalysts for ongoing debates about the extent to which human rights extend to sport participation and the development of policies by sporting bodies. The vast majority of controversies have centered on the participation of trans women in women's sports because of the assumption that past exposure to higher levels of testosterone constitutes an unfair competitive advantage over cis women competitors. Supporters of trans participation include leading scholars in the field, who, as discussed in the sections that follow, refute arguments about biological advantage and draw attention to the flawed science of sex difference that is employed to arbitrate questions of eligibility for trans and cis women alike in women's athletic competition.

The Assumptions of a Two-Sex System and Male Athletic Advantage

Objections to the participation of trans women in sport center on two taken-for-granted assumptions: that there are only two sexes and that men as a group have an athletic advantage over women as a group. These assumptions about binary sex differences inform a particular moral panic around the participation of trans women in women's sports. Even though Richards was not a particularly successful professional athlete, she was alleged to have an unfair advantage because of having been assigned male at birth, and the need to prevent the perceived advantage of trans women has become a persistent feature of policies designed to regulate their inclusion in amateur and professional sport. In contrast, trans men are viewed as either fundamentally limited in competition against cis men by having been assigned female at birth or as having their performance unfairly enhanced in competition against women if they take testosterone as part of their transition process. The debate about the inclusion of trans athletes involves questions as to the extent to which hormone therapy effectively changes biological characteristics associated with an assumed male athletic advantage.

Feminist science studies and critical sports scholarship have successfully troubled both the naturalness of the two-sex system and fundamental male athletic advantage. This research emphasizes two findings that are relevant to the participation of trans people in sport: first, that there is no clear line of demarcation between male and female bodies, and second, that existing gendered overlaps in athletic performance are systematically rendered invisible. The underlying assumption of sex-segregated sporting spaces is that someone who is born male naturally has an unfair advantage when competing against girls and women in sport. A number of scholars have refuted this assumption of athletic superiority. So-called male and female bodies develop in social contexts that assume and privilege male athletic competence at the expense of female physical development. Critical feminist sports scholars focus on the role of sport in contributing to gender inequality by reinforcing orthodox masculinity and perpetuating sexism. Within this field is an emergent subset of research that views the sex segregation of amateur, elite, and professional sport as deeply problematic.

The Role of the International Olympic Committee

Policies for the participation of trans athletes in amateur and professional sports have been greatly influenced by the International Olympic Committee (IOC). The IOC first developed a trans participation policy in 2004. Colloquially known as the "Stockholm Consensus," this policy required transsexual athletes to undergo complete hormonal transition at least 2 years prior to competing in an Olympic event, to undergo genital-reassignment surgery, and to have documents proving legal recognition of their new sex by their home governments. Many international and national sporting bodies followed the IOC's lead by developing identical policies. The Stockholm Consensus was widely criticized by sport scholars on the grounds that genitals are irrelevant to athletic performance, that the expense and/or invasiveness of surgery is a barrier for many athletes, and that many governments

refuse to supply legal documents designating the appropriate legal sex identity.

In 2016, the IOC announced that trans athletes would be eligible to compete in the Olympics without having undergone gender-affirming surgery. While it is seen by many as an improvement over the prohibitive requirements of the Stockholm Consensus, it continues to reflect an ideological commitment to a two-sex system (albeit a more complicated one) and an unquestioning belief in male athletic superiority. Trans women are required to follow a hormone regimen that negates the "performance-enhancing" effects of testosterone, whereas trans men are not required to submit to any hormonal regimen in order to participate as men in men's sports.

The policies and controversies regarding trans inclusion in sport overlap with those relating to gender verification testing for women athletes and supposed biological boundary markers between male and female athletes as they relate to eligibility for participation. Critical scholarship troubles binary sex categories and male superiority by observing that sex differentiation is far more complex, citing people born "intersex" as an example. There is considerable debate over what percentage of the population is born with intersex characteristics; the numbers are impossible to verify because many people with intersex conditions are invisible—that is, they are not characterized by ambiguous genitalia but feature so-called chromosomal "abnormalities" that are often never detected. Indeed, women athletes who "failed" the scientifically flawed gender verification tests that the IOC and its affiliated organizations required of all women competitors from the 1950s to 2004, and on a case-by-case basis subsequently, have often learned that they are intersex only as a result of this process itself. Obviously, the vast majority of people never experience such testing, so the data relating to the frequency of intersex conditions is fundamentally limited.

Openly Trans Athletes in Professional Sport

Since Richards's groundbreaking participation in the WTA, only seven trans athletes from four countries are known to have competed in professional sport, five in women's sports (Australian Mianne Bagger in golf, Canadian Michelle Dumaresq in mountain bike racing, American Fallon Fox in mixed martial arts, Brazilian Tiffany Abreu in volleyball, and Australian Hannah Mouncey in Australian rules football) and two in men's sports (Canadian Harrison Browne in ice hockey and American Patricio Manuel in boxing). Seemingly, many trans individuals have not sought to compete, or at least not been open in doing so, because of a fear of criticism and opposition. This is especially the case for trans women competing in women's sport.

In fact, all five out trans women professional athletes encountered discrimination and had to fight attempts to keep them from participating in their sport. For example, when Bagger first began competing professionally in the mid-2000s, most professional golf associations barred trans women players by stipulating that competitors must be "female at birth," a policy no doubt prompted by Richards's earlier success against the WTA. Bagger worked hard to educate the leadership of national and international professional golf associations to change this rule. Her efforts, combined with the 2004 ruling by the IOC enabling fully transitioned athletes to compete, led many golf associations to change their policies. It was not until 2010, however, that the Ladies Professional Golf Association amended its bylaws to allow trans women to compete.

Fallon Fox's career in mixed martial arts (MMA) was likewise negatively affected by transmisogyny. Even though she qualified to compete according to the requirements of the IOC and had been ruled eligible by state licensing bodies, she was prevented from having bouts by the refusal of the Ultimate Fighting Championship MMA promotion organization to include her on fight cards. She was also left off the list of Unified Women's MMA rankings as a result of open bias against trans women. The opposition contributed to Fox retiring in 2014.

In contrast to Fox's experience, Patricio Manuel has been more widely accepted, earning support from the MMA and a sponsorship deal with the fitness equipment corporation Everlast. This is consistent with assumptions, rendered in trans participation policies, that trans men have no advantage over cis men in competition, unlike pseudo-scientific claims that view trans women as having just such an advantage.

Sex Segregation in Sport

The experiences of these trans athletes reflect the foundational role of modern sport in normalizing

an ideological binary sex system and male athletic superiority. Sex segregation is one of the central features of major professional sports worldwide, such as ice hockey, football (including soccer, Canadian and American football, and Australian rules football), tennis, basketball, and golf. Female athletes are required to develop and compete in their own leagues and typically earn a fraction of the amount of money made by male athletes. The lone exception is tennis, where the popularity of the women's game, along with advocacy from women players and their supporters, has resulted in equal purses for men and women at major tournaments in recent years. The fact that the names of professional women's sports associations are specifically gendered while men's remain unmarked (e.g., the Ladies Professional Golf Association versus the Professional Golf Association, the Women's National Basketball Association versus the National Basketball Association) is a powerful example of how sport is assumed to be a masculine realm. Understood in this light, the maintenance of male privilege in professional sport depends on the fierce patrol of its gendered borders. The regulation of the bodies of women and trans people reflects the extent to which all people not categorized as male are interlopers.

Sex segregation in sport is grounded in a vision of sex as a binary system that conforms to Eurocentric norms, whereby males and females are considered fundamentally different kinds of humans, and that emphasizes difference via the deliberate invisibility of similarities between male and female athletes. Despite documented overlaps between male and female athletic performance, mainstream sporting policies continue to lean heavily on a Western trope of white female frailty. The ideology of the two-sex system is grounded in antifeminist gender essentialist theories that correlate naturalized and stereotypical masculinity with biologically defined males and femininity with biologically defined females—an argument that was used to keep girls out of sports prior to the 1970s.

The limited nature of inclusion permitted by the IOC continues to reinforce binary-based understandings of sex difference. Such trans inclusion policies tend to be conservative in that they reify, rather than challenge, the sex binary that is instrumental in gender inequality and anti-gay and anti-trans oppression. As a result, many trans people are left out when it comes to participation in amateur and professional sport, including those who do not conform to binary understandings of sex difference, who do not successfully "pass" as men or women, or who are unable to access trans-affirming health care.

It is simplistic but instructive to speak of two classes of trans people on the basis of family support combined with socioeconomic privilege. Barriers to accessing the affirming health care that ameliorates gender dysphoria and aids assimilation (whether that is the desired goal or not) include nationality, poverty, racism, lack of health insurance, lack of family support, geographic inaccessibility, binary nonconformity, immigration status, mental health issues/trauma, and coming to understand oneself as trans too late to redirect puberty. And nonbinary athletes typically have literally no place to play. Sport policy has not even begun to take these issues into consideration.

Authorship of Trans Literature

Scholars in science, medicine, and public health have brought renewed visibility to gender inequity among professional ranks within these fields. Some scholars, such as Geordan Shannon and Cléo Chassonnery-Zaïgouche, have referred to a process of "gender reckoning," calling attention to the phenomenon of critical gender analysis within academic disciplines and the concomitant imperative for better gender representation among faculty and other scholarly positions, to transform research priorities, values, and impact. In the trans health field, a recent evaluation analysis of published studies by Waleed Sweileh (2018) revealed that out of the top 10 authors who are major contributors to trans literature, only one researcher is openly transgender (trans)-identified. This analysis accounts for at least a century of peer-reviewed publications on trans health and represents a body of work that is rooted in cisnormativity and cisgenderism; trans publications reflect a predominantly cisgender (cis)–centered context of research, whereby cis researchers' perspectives are valued and privileged and trans researchers' voices are marginalized. This entry addresses factors implicated in, and problems resulting from, gender disparity in trans literature and in particular the lack of trans representation among authors of trans health scholarship. This essay also offers a blueprint for organizations and institutions to address this issue.

Factors That Contribute to Lack of Trans Representation in the Authorship of Trans Literature

Underadmittance of Trans Scholars in Advanced Degree Programs

To understand the disproportional gender composition in trans authorship, it is crucial to examine structures accountable for producing researchers, namely, research organizations and institutions. Specifically, this authorship disparity reveals who gets accepted into higher education institutions, attains advanced training and credentials to engage in trans research, and achieves authorship in peer-reviewed journals. According to the 2015 United States Transgender Survey (USTS), a national survey of over 27,000 trans people, as well as the 2019 U.S. Census data, trans people are underrepresented 2.5 times less in doctoral programs and 1.7 times less in professional programs compared with cis people. This disparity is driven by trans students' well-documented experiences of transphobia, discrimination, and mistreatment in higher education, which negatively affect their access to a range of opportunities (mentorship, inclusion in research collaborations and networks, authorship) and contribute to their retention and academic success. Lack of representation and success in these programs reduces trans students' chances of successfully competing for federally funded research awards and being hired as faculty. Admission committees, therefore, play an important point of influence given their power to challenge the status quo of cisnormativity and cisgenderism in higher education. Once admitted to advanced degree programs, academic administrators and leaders have significant roles in challenging tokenism of trans scholars in academia and in cultivating gender-inclusive and gender-affirming training environments that can maximize the success of young trans scholars.

Lack of Investment in Trans Research and Researchers at the Funding and Authorship Levels

At the funding and authorship levels, federal grant institutions and scientific journals are currently not collecting gender identity data from researchers to examine gender disparities in awardees and authorships beyond the male/female binary. A 2019 study by Travis Hoppe, titled "Topic Choice Contributes to the Lower Rate of NIH Awards to African-American/Black Scientists," demonstrated that African American/Black scientists, particularly women, receive lower grant scores and funding relative to their white counterparts. This disparity was mainly attributable to these scholars proposing community-level health interventions (e.g., addressing health disparity, reproductive health) rather than biomedical studies (e.g., focusing on stem cells, vaccines, molecular biology), possibly reflecting a value at higher levels of research funding and administration regarding which types of research are "worthy" of investment. Similarly, scientific journals are more likely to publish studies authored by cis men than by cis women. These findings have potential implications for trans literature, particularly in trans health research, given that establishing trust and collaboration between trans community members and scientists is crucial to

Table 1 Recommendations to Address Gender Disparity in Trans Health and Empower Emerging Trans Researchers

Recommendation	*Description*
For Research Organization and Institutions	
Use gender equity lens in recruitment and admission process.	– Set gender equity goals that explicitly measure number of trans students in admitted student pool. – Incorporate a transgender identification questionnaire in student application forms and/or school records. – Include trans faculty and trans students as part of admission review committees. – Allocate recruitment funding and resources that target prospective trans applicants.
Hire trans faculty and staff.	– Hire trans faculty and staff across all levels of the organization and/or institution. – Create a resource pipeline to retain and advance graduating trans students to become faculty and/or staff members. – Include trans faculty and trans students as part of hiring committees.
For Journals	
Collect gender identities in journal management systems.	– Collect gender identities beyond the female/male binary of authors submitting manuscripts and other publication pieces. – Track the number of submission outcomes (e.g., rejection, acceptance) by gender.
Invite and commission trans researchers and authors on trans health and/or related topics.	– Invite trans researchers and authors to write commissioned pieces regarding trans health and/or other relevant topics.
Invite trans researchers as reviewers and/or editors.	– Meaningfully invite and hire trans researchers as Reviewers, Editors, and/or staff across all levels of journal organization.
Challenge manuscripts written with cisnormative and cisgenderism framing.	– Recognize and challenge articles during the peer-review process to refrain from promoting cisnormative and cisgenderism framing throughout the manuscript, including definitions and recommendations that medically pathologize trans people and widen inaccessibility of trans-related health services.
For Federal Grant Institutions	
Collect gender identities in federally funded grant application systems.	– Collect and track gender identities beyond the female/male binary of lead and coinvestigator applicants who apply for federally funded grants.
Fund trans research that is trans-led.	– Establish research funding streams (e.g., request for proposals, early investigator awards) catered to trans research that is trans-led.
Invite trans researchers as study/grant reviewers.	– Meaningfully invite trans researchers as study/grant reviewers.
For Cisgender Researchers	
Cite trans researchers and authors.	– Support the work of trans researchers and authors by intentionally acknowledging and citing their manuscripts and other publications. – Unlearn cisnormative models/framework and learn new ones put forward by trans researchers and authors.
Recognize privilege in being a cisgender researcher.	– Recognize that cisgenderism and cisgendernormativity are pervasive in the field of trans research and literature and that this culture and practice are often upheld, protected, reinforced, and benefited by cisgender researchers.

Recommendation	Description
Mentor and make space for trans researchers and authors in writing manuscripts and designing trans research.	– Grant space for emerging trans researchers and authors to lead and/or co-lead manuscripts and other relevant projects. – Provide meaningful mentorship by treating trans mentees with autonomy and respect and deferring toward their expertise when appropriate.
Invite community trans collaborators and members to be authors.	– Meaningfully invite and include trans collaborators and community members to participate in research manuscripts and other projects, while simultaneously challenging tokenism in such participation.

Source: Authors.

study success. In addition, cis researchers are currently more often published in trans health than are trans researchers. In cases when trans people are included in federally funded studies, trans samples are often lumped with those intended for cis people (cis men-who-have-sex-with-men studies), contributing to a system in which trans issues are investigated as supplementary to cis-focused research. Additionally, there are no systematized data showcasing federally funded studies that invest in trans studies led by trans researchers. Without data to distinguish trans researchers at the funding and authorship levels, analogous studies examining disparities in authorship and the ratio of submission to acceptance/rejection by gender identity cannot be conducted.

Common Problems With Lack of Trans Representation in Trans Literature

Gender disparity in trans literature sheds light on who holds power and privilege in shaping this scholarship. The overrepresentation of cis authors reflects the ways in which narratives, terminology, theories, and recommendations are fomented from a cisnormative, cisgenderist viewpoint. These norms have been established as gold-standard research practices despite challenges from trans researchers and communities.

For example, in the field of trans health, the term *transgender* has consistently been defined on the basis of biological sex (e.g., "people whose gender does not match their sex assigned at birth") even though trans researchers and writers have detached biological sex as a qualifier and defined trans based solely on gender identification. Moreover, dominant narratives and medical constructions of trans people's transition experiences are framed similarly (e.g., born/trapped in the wrong body), contributing to what trans trailblazer and writer Janet Mock (2012) describes as a "convenient, lazy explanation [that] fails to describe trans people . . .that makes trans people's varying journeys and narratives palatable to . . . the cis masses" (para. 3). Nearly all trans research papers begin by defining trans populations according to this construction while cis studies do not define what cis means, thereby reinforcing cisnormativity in research.

Such cisnormative framing also feeds into clinical recommendations. For example, requiring a gender dysphoria diagnosis for access to medical gender affirmation (hormone replacement therapy, gender-affirming surgeries) creates additional barriers to health care and promotes stigma toward trans individuals. Trans scholars have criticized these requirements for pathologizing trans identities, widening health care inaccessibility, and reifying the gender binary to the detriment of trans individuals.

Conclusion

Given the ways in which hegemonic cisnormativity and cisgenderism have pervaded trans literature in general and trans health scholarship specifically, it is critical for the voices of trans researchers and writers to be pragmatically and intentionally uplifted, centered, and supported. Table 1 provides suggestions for moving the field toward this goal. These recommendations are an embarkation toward empowering emerging trans scholars as authors to the benefit of the trans literature.

Autobiographies

Since the 1930s, trans individuals have published autobiographies not only to tell or to clarify the stories of their lives but also to educate others in an effort to gain greater acceptance for trans people. Many of the early autobiographies were written by trans women, whose gender identities had been revealed by the press. Forced into the media spotlight because they were trans, their work often served as a response to the stereotypes and misinformation circulated about their experiences. In the 2000s, trans male autobiographies became more commonplace. Although comparatively fewer autobiographies have been published by nonbinary trans individuals, a growing number of such works in the 2010s, along with relatively more works by trans people of color and trans youth, have led to better representation of the diversity of trans identities.

Trans Autobiographies, 1933–1983

Given the unprecedented news coverage that Christine Jorgensen received beginning in 1952 for being the first publicly recognized person from the United States to have had what was then called a "sex change," it is not surprising that her 1967 life story would be the most widely known among the

early trans autobiographies. But the earliest trans autobiographies were published by Europeans; the first known book-length account is the narrative of Lili Elbe, a Danish painter who became one of the first individuals to undergo gender-affirming surgeries. Shortly before her death following one of these surgeries in 1931, Elbe requested that her friend Ernst Ludwig Hathorn Jacobson develop a book based on her diary entries, letters, and dictated material. Jacobson published the resulting work, *Man Into Woman: An Authentic Record of a Change of Sex,* posthumously under the pseudonym Niels Hoyer.

After *Man Into Woman,* another trans autobiography was apparently not published until 1954, when two works were written by British trans people in the wake of the international publicity surrounding Jorgensen's transition. Robert Allen's *But for the Grace: The True Story of a Dual Existence* describes how he was assigned female at birth but petitioned the British government to amend his birth certificate in 1944—one of the country's earliest officially recognized gender changes. *Roberta Cowell's Story by Herself* is an account by the woman who had the first known vaginoplasty in England and who was legally recognized as female in 1951.

Being the first British trans woman to undergo surgery and having achieved some fame previously as a race car driver, Cowell's transition made headlines in Britain. The outing in the British tabloid press of models April Ashley and Caroline Cossey (known as Tula) generated similar public interest. Both recounted their experiences in 1982 autobiographies: *April Ashley's Odyssey* and *I Am a Woman,* respectively. Even more attention was paid to the transition of renowned British author and travel correspondent Jan Morris, who wrote the best-selling *Conundrum* (1974).

In the United States, the best-known trans autobiography in the late 20th century was Renée Richards's *Second Serve* (1983). Richards became famous in the 1970s for successfully suing to overturn a ban on her playing professional women's tennis because she was a trans woman. But rather than discussing her court case or her pro tennis career, Richards devoted the majority of *Second Serve* to detailing her struggle to accept her gender identity. She detailed her subsequent life in *No Way Renée* (2007). Lesser known autobiographies of the era by U.S. trans women included socialite Dawn Langley Simmons's *Man Into Woman* (1971), singer Canary Conn's *Canary* (1974), journalist Nancy Hunt's *Mirror Image* (1978), and Sharon Davis's *A Finer Specimen of Womanhood* (1986), the first known autobiography by a Black trans person.

Notably absent from the 1960s through the 1980s were published narratives by trans men, with the major exception of Mario Martino's *Emergence* (1977), which focused on his struggles to reconcile his sense of himself as a man with his conservative Catholic upbringing. A few trans male autobiographies were published in the 1990s, most notably Paul Hewitt's *A Self-Made Man* (1995), Mark Rees's *Dear Sir or Madam* (1996), and Dylan Scholinski's *The Last Time I Wore a Dress* (1997). The latter book tells the horrific story of how Scholinski's family institutionalized him during his high school years for his gender nonconformity.

Contemporary Trans Autobiographies

While not strictly autobiographies, the publication of Leslie Feinberg's semi-autobiographical novel *Stone Butch Blues* (1993) and Kate Bornstein's collection of personal essays and performance works *Gender Outlaw: On Men, Women, and the Rest of Us* (1994) helped usher in a new generation of trans narratives that were more than stories of personal acceptance and transition and that largely did not ascribe to stereotypical notions of gender, even if the author identified as a binary trans person. Moreover, the popularity of Feinberg's and Bornstein's works, along with the growing visibility of trans people, led publishers, including many major presses, to take a greater interest in trans books, and an unprecedented number of trans autobiographies were published in the early 21st century. The ease with which people can self-publish today has also contributed to the rapid growth in the number of books about individual trans experiences.

At the same time, the writers of trans autobiographies have become much more diverse. In the 20th century, there were only a few autobiographies by trans people of color published, notably Davis's work and the Lady Chablis's *Hiding My Candy* (1997). Although there continues to be a

scarcity of autobiographies by trans people of color, the works of two of these authors have been among the most acclaimed in the genre. Janet Mock's *Redefining Realness* (2014) vividly illustrates the intersections of racism, classism, and transmisogyny, as she recounts how she struggled in her teens as a Black trans woman to pay for hormones and gender-affirming surgery and was only able to do so through sex work. In 2017, Mock released a follow-up memoir focusing on her experiences in her 20s, *Surpassing Certainty.* Willy Wilkinson's *Born on the Edge of Race and Gender* (2015) likewise offers an intersectional analysis of his experiences as an Asian American trans man, which includes having a chronic illness, medically transitioning, and being a father. Other notable autobiographies by trans people of color include Toni Newman's *I Rise* (2011) and Ryka Aoki's *Seasonal Velocities* (2012).

Similarly, while there had been few trans male autobiographies published in the 20th century, a number of such works have come out since then, including Jamison Green's *Becoming a Visible Man* (2004), Matt Kailey's *Just Add Hormones* (2005), Max Wolf Valerio's *The Testosterone Files* (2006), and Dhillon Khosla's *Both Sides Now* (2006). Green's book was especially significant because he told not only his own story but also the history of trans male community building, in which he was a central figure.

Reflecting how more and more trans people are identifying as nonbinary, a growing number of trans autobiographies are by nonbinary individuals. The most celebrated of these works is Jacob Tobia's *Sissy* (2019), which they subtitle "a coming-of-gender story," as the book relates how they came to embrace their femininity and take pride in their gender nonconformity, such as simultaneously having facial hair and wearing high heels. Another acclaimed nonbinary autobiography is Maia Kobabe's graphic memoir *Gender Queer* (2019), which describes coming-of-age experiences like starting school, getting one's period, and beginning to date from the perspective of someone who is nonbinary and asexual.

Still, the vast majority of trans autobiographies continue to be published by trans women. Among such works published since the late 1990s are books by Jayne County, Deirdre McCloskey, Aleshia Brevard, Calpernia Addams, Donna Rose, Beth Elliott, Kristin Beck, and Sarah McBride. The most prolific and best-selling trans autobiographer is English professor and *New York Times* Contributing Opinion Writer Jennifer Finney Boylan. Beginning with *She's Not There* (2003) and continuing with *I'm Looking Through You* (2008), *Stuck in the Middle With You* (2013), and *Good Boy* (2020), Boylan has discussed such topics as her marriage (which continued after her transition), parenting, and her experiences with having dogs throughout her life. Another trans female autobiographer of note is poet and English professor Joy Ladin, who described her struggles with being true to herself and how her transition affected her family, career, and Jewish beliefs in *Through the Door of Life* (2012). Ladin, the first openly trans person to be teaching at an Orthodox Jewish university, further formulated her thoughts on being trans and Jewish in *The Soul of the Stranger: Reading God and Torah From a Transgender Perspective* (2018). Another important Jewish trans narrative is Abby Stein's *Becoming Eve: My Journey From Ultra-Orthodox Rabbi to Transgender Woman* (2019).

Because of the plethora of trans autobiographies since the early 2000s, a trans person today has to have a unique experience in order to interest most major publishers in their stories. A case in point is Thomas Beatie, a trans man who became famous for becoming pregnant and giving birth to a child after transitioning. His life story, *Labor of Love* (2008), was published soon after his first child was born.

As in the past, trans people who were famous before they came out publicly as trans became even more known afterward and took advantage of their celebrity status (and ghostwriters) to publish their autobiographies in the 2000s. Chaz Bono, the child of Sonny Bono and Cher, wrote *Transition* (2011), and gold-medal-winning Olympic decathlete and reality television star Caitlyn Jenner wrote *The Secrets of My Life* (2017). Jenner's book became a bestseller but more because of her star power than the quality of her narrative.

Another celebrity to write an autobiography, YouTube and reality television personality Jazz Jennings, was part of a new trend in trans autobiographies in the 2010s: books by trans youth. Her book, *Being Jazz* (2016), recounts not just her moments of fame but also her struggles to be

seen as female, which included the need for her family to fight for her right to play girls' soccer. Two other trans youth autobiographies are Katie Rain Hill's *Rethinking Normal* (2014) and Arin Andrews's *Some Assembly Required* (2014). The two books are companion pieces: The writers—a trans woman and trans man, respectively—medically transitioned in their mid-teens and dated each other, which both discuss in their works, which they wrote in their late teens. Hill's account is the more heartbreaking: Because of bullying from other youth and internalized self-hatred, she tried to take her life at 8 years old and continued to suffer through her tween years before accepting herself. But the most heart-rending youth narrative is Zane Thimmesch-Gill's *Hiding in Plain Sight* (2015), in which he describes being homeless as a teen and having to survive on the streets because he could no longer tolerate his family's hostility. The autobiographies by trans youth vividly demonstrate the importance of parental support. For these authors, it was the difference between being able to socially and medically transition relatively easily versus having to struggle to embody one's identity.

The Evolution of Trans Autobiographies

Trans autobiographies, like trans people themselves, have significantly progressed over the past 75 years. As trans people have become less of a sensation in the dominant society, so too have their personal narratives focused less on the spectacle of being trans. Today, trans autobiographers can write memoirs that address the complexities of their lives and can be more than their gender identities.

Ballroom

Ballroom refers to a culture of ball/house competitions and dances performed by racial, gender, and sexual orientation minorities, particularly by African American and Latina/o/x LGBTQIA individuals. Central to ball competitions is voguing, a unique type of dance that involves poses that span a variety of styles, including modeling and acrobatics. Since the 1920s in Harlem, balls have provided an outlet for the expression of gender identity and sexual orientation through performance themes or categories. This entry provides an overview of ballroom culture, the importance of House families, ball categories, and research on HIV risk in the community.

Ballroom culture was primarily underground until the documentary *Paris Is Burning* by Jennie Livingston was released in 1990. Within the documentary, key figures within the ball community were interviewed, casting attention on voguing, racism, gender and sexual orientation–based violence, and the importance of House families. The documentary also highlighted the impact of the HIV/AIDS pandemic on LGBTQ African American and Latino ball members. Similarly, Madonna brought additional mainstream attention to ballroom culture in 1990 with her music video *Vogue,* which featured Madonna and other ball members performing vogue and other ballroom dance moves. Currently, balls are held across the United States in most major cities, including Atlanta, Los Angeles, Oakland, Chicago, Philadelphia, and Washington, D.C.

Ball culture flourished during the Harlem Renaissance in the 1920s, with balls being held in New York City, Chicago, Baltimore, and other cities. These interracial balls were attended by thousands and often attracted an even greater number of onlookers. For example, a newspaper account of a 1929 ball held at New York's Rockland Casino estimated that 2,000 "fairies" participated, while 3,000 people looked on at their "girlish antics."

Because of opposition from local authorities, large-scale drag balls were not held in Washington, D.C., in the 1920s and '30s. Instead, ball culture developed there around 1960 and consisted of lip syncing drag performances. D.C. became a ballroom capital, with annual balls still being held to this day.

House Families

Those who compete in balls often maintain membership in a House, a kinship structure that serves as an alternative social family. Houses provide a variety of support for members, including emotional, social, or physical support, including a physical place for House members to reside. House members have intersecting and marginalized identities that are accepted and celebrated within ballroom culture.

Houses consist of a "mother" and/or a "father" who serve as mentors for the "children" of the house, organize ballroom events, recruit new House members, and assign responsibilities. Parental roles within the house are not determined by gender and are instead assigned based upon feminine or masculine traits that outline the division of House labor. House "mothers" may include butch queens (gay men) or femme queens (trans women) who provide nurturing and emotional sources of support. House "fathers" may include butch queens or trans men who serve as both protectors and leaders. House structure may vary, with some Houses having multiple parents or alternative leadership figures (i.e., godfather/godmother, ambassador, and/or prince/princess).

Research has found that Houses often serve as a replacement for the member's biological family, as Houses provide a haven for members to go for holidays or during difficult periods of life. For example, House members are often subjected to discrimination based upon their sexuality or gender identity from their biological families, which may result in homelessness or familial rejection. Association with a House can contribute to a sense of belonging, reduce stigma, and aid in gender expression. Within ball performances, competitors can explore gender expression by competing in multiple categories without judgment.

Balls and Voguing

House members host and participate in balls, performance-based competitions, that include dancing, style, and creativity. Individuals compete for a panel of judges, usually House parents or leaders, to obtain cash, trophies, and prestige for themselves and/or their house. Judges rate each performance on a 10-point scale, with special attention paid to category/theme adherence, creativity, and likeability of the performer. The competitor with the highest score advances to the next round to continue competing until a victor is announced. Winning provides status, which aids in recognition both for the performer and for their House. Free agents, those who are not affiliated with a House, may compete to attract the attention of a particular House.

Balls include various performance categories that include Fashion and Runway, Realness, Performance and Vogue, Face, Body and Sex Siren, and Virgin categories. These categories are further specified by themes within each category. Ball category and theme lists are often distributed at least 1 month prior to Houses and include standards that performers are later judged on.

Fashion and Runway categories involve runway performances in front of both judges and observers to test participant knowledge of fashion and confidence in walking the runway. This category features the participants' ability to walk the runway like a high fashion supermodel. Themes within the Fashion and Runway category include European/American runway and Butch Queen in Pumps, where competitors perform in high heels.

Performers in the Realness category compete to "pass" as heterosexual and/or cisgender across a variety of domains (e.g., Executive, Femme Queen, and Butch Queen). For example, a trans woman may compete in Femme Queen Realness to pass as a cisgender woman through appearance, attitude, and mannerisms. The Realness categories provide opportunities for trans individuals to test their ability to pass, regardless of medical or social transition status.

Dance and athleticism skills are tested in the Performance and Vogue categories through dance battles and voguing. Voguing, named after the fashion magazine *Vogue,* combines posing, modeling, and dance through five key components: catwalk (runway), dip, hand placements, duck walk (moving low to the ground while voguing), and spins.

Performers seek to embody youth and beauty when competing in the Face categories by showcasing or "selling" their faces as a key feature while performing on the runway like a supermodel. To draw attention to the face, competitors seek to angle their face and use their hands/arms to highlight key features, such as their eyes, teeth, skin, nose, or bone structure. Key categories include Femme Queen Face (trans women), Butch Face (butch cisgender female), Butch Queen Face (cisgender male), and Women's Face (cisgender female).

Within the Body and Sex Siren category, individuals showcase their bodies and muscles in revealing clothing. Butch Queen/Femme Queen Sex Siren categories require individuals to perform in undergarments, such as thongs, briefs, or

bikinis, to demonstrate sex appeal. The physique expected for categories may vary, with some categories requiring participants to be more or less muscular.

Ball newcomers may compete in the Virgin category to make a name for themselves and potentially be recruited by a House. Those who compete in this category have never performed at a ball before.

HIV in the Ball Community

Research has explored HIV prevention practices within ballroom culture, including the role that House parents play in reducing risk and educating members. Previous research has found that ball community members are unlikely to be tested for HIV and are especially unlikely to be tested within the past 12 months. African American ball members are less likely than Latino/a members to know their HIV status. Risk factors identified in the research include illicit drug use and engagement in unprotected sexual behavior. Research has indicated that escorting and sex work are common within the ball community and may be used to fund clothes and travel expenses. The accessibility of the Internet has been cited as a reason for increases in escorting services within the ballroom community because of the ease in concealing the activity.

HIV prevention efforts occur within the House hierarchy, such as through hosting HIV prevention balls to raise awareness and provide resources. House "mothers" may provide information about HIV risk and prevention to members, including encouraging condom use and ways to safely manage sexual encounters that reduce the risk for HIV and exploitation. House "mothers" reduce the risk of transmission by providing transportation to HIV testing appointments and helping members locate additional resources. House "fathers" have been found to protect against structural issues that may place individuals at risk for HIV, such as encouraging education and economic opportunities. In addition, "fathers" encourage members to volunteer and give back to the ball community. Houses provide a stigma-free environment to seek information about HIV that members cannot discuss with their biological family outside of the ball community.

Modern Ballroom and Technology

Technology has expanded the reach of the ballroom community by providing online platforms that connect ball members across the globe. Internet platforms such as Facebook and YouTube have assisted in bringing ballroom culture more into the mainstream of society. Ball performances may be recorded and shared on social media platforms to draw attention and support. Shows such as *Pose* on Netflix have continued to provide representation of life inside the ball community and for outsiders to view. Ball culture has expanded outside the United States and into countries such as Canada, Italy, Japan, and the United Kingdom.

Bathroom Discrimination

Trans activists and critical gender scholars have documented the way bigender toilets function to exclude those who are gender variant or seen to

be at odds with the dimorphic gender signs on toilet doors. Transphobia in gendered toilets is well documented. The bigendering of toilets functions to regulate, to police, and to excommunicate those who do not conform to gendered signage. Although the gendering of elimination is a historically recent phenomenon, it is now so commonplace in North America that people presume such gendering to be normal and natural. As many commentators have noted, however, there are no legitimate health and safety rationales for gendering toilets, much less for excluding people on the basis of gender identity. This entry discusses the sociohistorical and legal context relating to bathroom discrimination with attention to gender, race, sexuality, censorship, and feminism.

Historical and Sociological Context

The literature on trans people and bathrooms demonstrates that there are interlocking elements of exclusion relating to white settler colonial logics, racial segregation, capitalism, consumer culture, heteronormativity, disability, occupational privilege, and socioeconomic status, which have contributed to patterns of discrimination. That is, transphobia in the North American bathroom needs to be understood in relation to historically and culturally specific forms of exclusion based on race, class, sexuality, ability, and so on. In the days before indoor plumbing, urination was not gendered or privatized in the way it became during the 20th century. Chamber pots, privies, and latrines were commonplace up until the late 1800s. In the United States, toilets were gendered but also racialized and subject to class-based divisions from the late 19th century until the mid-20th century. The racially segregated toilets and water fountains in the southern American states during the Jim Crow era (1870–1965) are a case in point. Toilets designated for "colored" were not always gendered, but toilets allocated for "whites" were almost always gendered. Following the civil rights movement and the corresponding decline of racially segregated spaces, public toilets continued to be gendered but not officially racialized. Most North American court houses, colleges, and public buildings were designed for white, able-bodied men who were permitted to work in and occupy the buildings.

Capitalist consumer culture was also a factor in the gendering of toilets. In Toronto, Canada, public toilets for women were first built by the retail entrepreneur Timothy Eaton so that female customers could shop for longer periods of time. The "Ladies Gallery and Waiting Room" became a fixture in the popular Eaton's department store in 1883. The Bloomingdale's department store in New York City offered facilities for women shortly thereafter. White women were recognized to be consumers and, increasingly, able to work for pay in the public sphere. This led to the development of new laws and building codes requiring gender parity with respect to public facilities. As a result of gender-parity legislation beginning in the late 1880s, it became common to see gender-segregated toilets. It also became common to see signs designated for "customers only" in restaurants, cafes, bars, and so on. Some employers adopted policies prohibiting custodians from using the toilets they cleaned. Contemporary trans scholars doing work in disability studies have also noted the way toilets in some public spaces are inaccessible to people with mobility restrictions. The problem is compounded when people have personal care assistants who are differently gendered than they are and thus cannot use the same toilet facility.

Gender, Sexuality, and Toilet Design

The relationship between the regulation of sexuality and the regulation of gender and excretion cannot be doubted. For example, French philosopher and sociologist Michel Foucault commented upon the panic about gay male sex in his discussion of the modern toilet. He focused upon the invention of the short cubicle door built into French boys' boarding schools to survey, monitor, and police any illicit touching. Worries about homosexuality and the criminalization of public sex in toilets have been well documented by scholars who study sexual regulation. For example, gay men have been subject to police entrapment and arrest dating back to the early public urinals in London and Paris. The criminalization of men who have sex with men in public urinals demonstrates the way sexuality is regulated and subject to policing in toilets. The history of cruising, tearooms, cottaging, and the criminalization

of public sex, enforced by police, is well documented in the LGBTQ literature.

According to some theorists and activists, anti-sex morality and heteronormative presumptions are reflected in the architecture and designs of toilets. The receptacles themselves seem to reflect cisgender and heteronormative body politics. Men stand upright to urinate in open view while women must use toilet bowls hidden by stall partitioning and a closable door. The urinal, as a larger or more publicly visible receptacle, amplifies and exaggerates the presence of cis-masculine genitals while the glass mirror (more prominently displayed and less likely to be broken in the women's room) aligns feminine-identifying people with an imagined phallic lack. Those who appear to be at odds with the gender signage on a given door are subject to the threat of harassment, assault, or arrest.

The biopolitical management of the body and its modes of evacuation in the modern lavatory are part and parcel of the regulation of gender, sexuality, class, and race in the modern era. The elimination function is an area of the body politic that is often thought to be inappropriate for scholarly investigation. There has been a concordant silence surrounding toilet studies in many scholarly venues, offset only by a select few critical geography and architectural studies, LGBTQ studies, disability studies, critical race, and post-colonial studies scholarship. These overlapping fields critically analyze the white, cisgender, and able-bodied politics shaping restrictive toilet designs.

Bathrooms and Censorship

Language, like gender and sexuality, has been subject to censorship. While sexuality studies have gained currency in academic circles, excretion is not often recognized to be a legitimate area of investigation. The reluctance to study and acknowledge the toilet in everyday discussion has curtailed social justice initiatives relating to public space accessibility, particularly for trans people and those with disabilities. Reluctance to acknowledge the institution of the toilet in the history of modernity is reflected in language itself. There is no word in the English language to designate the toilet that is not also a euphemism.

Gender, Toilets, and the Law

Much activist work in the U.S. context has been focused on the "bathroom bills"—legislation that seeks to prohibit trans patrons from using toilets consistent with their gender identity. Most efforts to enact such laws have failed, but, in 2016, North Carolina passed a law that required individuals to use the restrooms in government buildings (including public schools and colleges) that matched the sex identified on their birth certificates. Due to nationwide protest and trans-positive activism, that provision of the law was rescinded the following year.

In Canada, trans people also face barriers to accessing public toilets. With the passing of Bill C-16 in 2017, an act amending the Canadian Human Rights Act and Criminal Code, "gender identity" and "gender expression" are prohibited grounds for discrimination. This gives people the legal right to access gendered toilets as they deem appropriate. Although trans and gender-variant people in Canada still face discrimination and harassment when accessing toilets, the legislation sets the groundwork for trans-positive education and public space accessibility.

Transgender studies help us to understand how cisgender presumptions about bigender culture are dangerous and at odds with the realities and needs of gender-diverse populations. The American actress and trans activist Laverne Cox has stated that the bathroom issue is about the rights of trans people to exist. That is, people must be able to use bathrooms consistent with gender identity. This is not only a civil rights issue but also a question of gender self-determination. Transgender studies scholars, activists, and a range of trans-positive gender theorists of all disciplinary backgrounds have developed innovative scholarship and proposals to deal with toilet accessibility following the attempt of the Trump administration and the courts to curtail Title IX protections developed under the Obama administration. Take, for instance, the project STALLED (https://www.stalled.online/) launched by Joel Sanders, Susan Stryker, and Terry Kogan. This equity-oriented project is led by an interdisciplinary team focused on making inclusive toilet designs for everyone regardless of trans status.

Feminism, Trans Studies, and the Bathroom

Some cisgender feminist researchers view trans-inclusive legislation as an attack on women's rights. This viewpoint does not recognize trans women as women. Nor does it recognize the realities of transphobia in bigender toilets. Differences between cis and trans-positive feminists are abundantly clear in discussions about health and safety. Many people, cis feminists included, believe that bigender toilets exist to ensure women's safety. The presumption is antiquated and not sustained in the literature on violence conducted by a range of feminist scholars. There is no convincing evidence to show that gender-segregated spaces are safer for anyone, let alone women. In fact, evidence shows that gender-segregated spaces can be more dangerous for women and trans people alike. Men physically and sexually assault women in the so-called ladies' room because a sign on the door acts as a symbolic and not an actual barrier.

Violence and harassment against trans women are often rationalized by the allegation that they are in the "wrong" bathroom and that they pose a risk to cisgender occupants. Police, security guards, and male vigilantes have all removed trans patrons from public facilities because they are allegedly in the wrong toilet. Bigender signage is not inclusive of trans patrons. Frequently, there is no "right" toilet for gender-variant people to use. Moreover, the presumption that trans people pose a threat to cisgender women is used to justify the forceful removal of trans patrons from toilets and to prevent access altogether. There is no research indicating that trans people in toilets pose a health and safety risk to anyone, let alone cis women. There is, however, evidence documenting cisgender harassment, intimidation, and assault against those who are trans and gender variant in public facilities. Cis women have justified harassment and assaults on trans people by stating that they are worried about their own personal safety. Even in the absence of intimidating communications and physical gestures normally accompanying assaults, defensive and unsubstantiated rationalizations for transphobia are given by cisgender patrons.

Research on violence against women demonstrates that the most dangerous public spaces are those that are dark, enclosed, and isolating as opposed to those that are well lit, open concept, and public. Gender-inclusive and accessible designs are thus safer for everyone regardless of gender identity and trans status. Bigender designs do not promote health and safety. Rather, they reflect cisnormative ideas about what it means to be a man and a woman.

Benjamin, Harry

Harry Benjamin (1885–1986), German American endocrinologist and author of *The Transsexual Phenomenon* (1966), is often remembered as the "father of transsexualism." He was a strong advocate for medically treating transsexual people at a time when accepted expert opinion was that being trans was a mental illness that should not be accommodated in any way.

Benjamin, born in Berlin, studied tuberculosis for his medical degree, which he received in 1912, *cum laude*. While a student, Benjamin met Magnus Hirschfeld, one of the leading sexologists of the early 20th century, who became a strong influence on Benjamin. Along with a senior police officer, Hirschfeld took Benjamin on tours through bars populated by people then known as homosexuals and transvestites. Benjamin also spent much time at Hirschfeld's Institute for Sex Research and admired Hirschfeld's bold advocacy on behalf of sexual and gender minorities. Another influence on Benjamin was Eugen Steinach, who became famous for his experiments demonstrating the effects of sex hormones in animals and for the "Steinach operation," which was reputed to rejuvenate elderly men by increasing testosterone production. Other lesser influences included Sigmund Freud, Albert Moll, Albert Ellis, and Margaret Sanger. However, it was Benjamin's meeting with Alfred Kinsey that propelled him into his work with trans people.

Benjamin relocated to New York City when complications related to the outbreak of World War I prevented him from returning to Germany after a trip abroad. He opened an endocrinology and geriatrics practice in New York, largely doing Steinach operations, and opened a second office in San Francisco. Benjamin met Kinsey when they stayed at the same hotel in San Francisco while Kinsey conducted interviews for his famous sexuality studies. Kinsey asked Benjamin to consult on a case of a young man who wanted to become a girl and whose mother supported this desire. Benjamin treated the patient with estrogen, observed that it had a "calming effect," and recognized that the condition was something other than crossdressing. This marked a turning point in Benjamin's career.

Over the next 30 years, Benjamin's practice included over 1,500 people with experiences that would now be known as gender incongruence or gender dysphoria. At over 60 years of age, Benjamin rapidly became the world's leading expert on people who wished to change their sex, lecturing and publishing widely on the topic for both professionals and the public. Contrary to accepted professional opinion of the day, Benjamin considered transsexualism to be a biological condition, not a mental illness, and actively advocated for acceptance and accommodation of trans people and their transition requests. Furthermore, he argued that psychological treatments were more often damaging than helpful.

Far ahead of his time, he wrote in a 1953 paper in the *International Journal of Sexology,* "It would frequently be wiser and more constructive to 'treat' society, educationally, so that logic, understanding, and compassion might prevail" (p. 14). Additionally, he was ahead of his time in his view that there were multiple kinds of sex—chromosomal sex, anatomical sex, legal sex, endocrine sex, germinal sex, psychological sex, and social sex—and that all humans were a mixture of male and female. Contrary to contemporary thinking, Benjamin did not see hormone treatments or what he called "conversion" operations as changing a person's sex. Rather, he believed that such treatments made people into "neuters" and were necessary for the peace that they brought. True to his times, he encouraged people who transitioned to be as inconspicuously gender conforming as possible.

The publication of his 1966 book, *The Transsexual Phenomenon,* was groundbreaking in many ways: It was the first book on the subject, it was written to be readable for the general public, it was sympathetic to trans people and argued for compassionate and supportive treatments, it featured extensive use of the words of trans people themselves, and it credited trans people such as Christine Jorgensen and Virginia Prince as authorities on the subject.

Modeled on Kinsey's famous 7-point Heterosexual–Homosexual Rating Scale, Benjamin included a 7-point "Sexual Orientation Scale" that classified people's gender from cisgender to transsexual. He further classified trans people into six types based on the intensity of their "gender

disorientation": pseudo-transvestites, fetishistic transvestites, true transvestites, nonsurgical transsexuals, moderate-intensity transsexuals, and high-intensity transsexuals, with only the last two types requiring hormonal and surgical interventions. Benjamin's book was supplemented with a special section only available to physicians. It included photographs of surgical results and basic information about hormonal treatment protocols to help sympathetic practitioners to know how to begin to medically treat transsexual patients.

Benjamin quickly became a hero to the many trans people who flocked to him. He was one of the very few doctors who responded with kindness, compassion, hope, treatments, and referrals. He answered all of the multitudinous letters sent to him, and he provided "doctor's notes," modeled after those provided by Hirschfeld, to satisfy police that the bearers were crossdressing for legitimate medical reasons. Benjamin also worked with trans people and with other professionals to help build facilities and support networks. The Harry Benjamin Foundation, supported by trans man Reed Erickson's Erickson Educational Foundation, became the incubator for the gender clinic at Johns Hopkins University, the first in the United States to perform what were then called sex reassignment surgeries.

In 1979, Harry Benjamin's foundational role in the field was recognized when the first professional association concerned with trans people was formed and named the Harry Benjamin International Gender Dysphoria Association (now known as the World Professional Association for Transgender Health [WPATH]).

Binding

Binding, or chest binding, is the practice of compressing the chest tissue for a flatter appearance as a means of gender expression. This is often accomplished by wearing a tight, specialized garment called a binder that looks like a tight tank top, which either extends over the whole torso or is cropped above the stomach. However, individuals use a variety of methods to bind, including wrapping elastic bandages or duct tape around the chest, wearing sports bras or surgical compression vests, or simply layering multiple shirts. One Australian study indicated that perhaps 87% of trans individuals assigned a female sex at birth use binding at some point in their lives.

Motivations for Binding

Trans individuals use binding to achieve a variety of goals. Many people begin binding as a way to explore an emerging or evolving gender identity, allowing them to literally "try on" a more masculine appearance. For some, gender dysphoria related to their chest can be reduced by minimizing the appearance of the chest. For others, binding may be less about managing an internal sense of dysphoria and more about managing other people's reactions to them. By appearing more masculine, binding may allow the wearer to avoid being misgendered or even allow them to avoid verbal or physical transphobic violence. Particularly for individuals who have undergone masculinizing hormone therapy or otherwise appear masculine but have not had top surgery (i.e., double mastectomy), binding may allow them to move safely throughout the world or

avoid being outed to their employer or other individuals.

Health Impacts of Binding

In addition to reducing gender dysphoria, binding has been reported to reduce anxiety, depression, and suicidality for many individuals, as well as generally improved mood and quality of life. This makes binding critical for mental health and safety in many individuals. Unfortunately, binding often has negative physical health impacts. In one study of 1,800 trans individuals who practiced binding, 97% reported at least 1 of 28 negative symptoms related to their binding, although these symptoms ranged from severe symptoms like rib fracture (3%) to symptoms of potentially minimal clinical importance, such as bad posture (40%). However, 74% reported experiencing binding-related pain in their shoulders, back, chest, or abdomen. Other symptoms included overheating (54%), shortness of breath (47%), lightheadedness or dizziness (28%), and scarring (8%). Skin changes (15%) caused by binding may be particularly concerning for trans individuals who hope to undergo top surgery, as changes to skin elasticity can compromise surgery outcomes. Individuals with larger chest sizes appear to be at greater risk of skin-related problems as a result of binding. Most of the 28 symptoms studied appear to emerge relatively quickly, within the first year of binding. Pain intensity appears to get worse on average over the course of several years.

Safer Binding

There is currently limited evidence indicating which binding practices are safer and which are more likely to cause physical harms. It seems clear that duct tape and elastic bandage wraps are some of the riskiest binding methods. While binders are perceived to be a safe option by the community, their use is still associated with many physical symptoms. More work is needed to understand whether this finding is driven by unsafe binder use (e.g., wearing two binders at once or wearing a size too small) versus using a single, appropriately sized binder. The safest binding methods may be those that offer less compression, such as sports bras or shirt layering. However, these methods may not offer sufficient compression to meet every individual's goals around gender, mental health, and safety.

One study found that binding fewer days per week was associated with lower risk of experiencing negative physical symptoms. Therefore, the current evidence best supports that individuals who are able to take "off" days from binding each week should do so to minimize physical harms. There was no apparent association between the number of hours per day that an individual practiced binding and whether they experienced negative symptoms; however, commonsense recommendations in the trans community often focus on binding no more than 8 to 10 hours at a time or taking one's binder off while sleeping to reduce the number of hours per day spent binding. Other binding safety measures include washing the binder regularly to avoid skin irritation or infection. These safety recommendations will continue to develop as new data become available.

Working With Individuals Who Use Chest Binding

In the study described in the preceding section, some 82% of individuals who used binding thought that binding was important to discuss with their health care provider, yet only 15% had done so, perhaps out of fear or uncertainty as to how their provider would approach the issue. Clinicians and service providers are advised to initiate conversations around binding and take a nonjudgmental approach to the issue, taking care to use language that affirms the individual's gender, including using the term *binding* or *chest binding* rather than *breast binding*. Providers should seek to understand the individual's goals and motivations around binding and how binding may be affecting the individual's life in positive or negative ways. Given the positive impacts to mental health and safety for many individuals, eliminating binding should not be the goal in most cases. Providers can support safer binding by sharing evidence-based information about the risks of binding so that individuals can make informed decisions about their binding. Providers can help brainstorm ways to meet as many of their patients' goals as possible around gender expression, mental health, and physical safety while also seeking to reduce any

physical health harms experienced. Providers may support the individual in thinking about how they might alter their routine in such a way to permit them to take more "off" days from binding or encourage them to switch from riskier methods such as elastic bandage wrap to less risky methods, at least for part of their time spent binding, if these changes can be accomplished safely. Providers can also cultivate a therapeutic alliance that enables the individual to feel safe reporting and receiving care for binding-related symptoms. Given the central role that binding can play for many trans individuals in their gender identity, gender expression, mental health, and safety, providers should support trans individuals to make informed decisions around binding in a way that best supports all dimensions of health.

Black Lives Matter

Black Lives Matter (BLM) is a term initially popularized by the hashtag #Blacklivesmatter and used to raise awareness of police violence and the lack of accountability for the murders of Black people. The hashtag went viral in social media and other media outlets in the summer of 2013 after vigilante George Zimmerman was acquitted of all charges for the fatal shooting of unarmed Black teenager Trayvon Martin in Sanford, Florida. BLM has since grown into a movement that focuses on fighting anti-Black racism while, at the same time, maintaining an intersectional politics that creates a space for often minoritized populations within Black communities, including Black trans people.

The hashtag was coined by Black queer woman organizer Alicia Garza, who, along with two other radical Black feminist organizers, Patrisse Cullors (who also identifies as queer) and Opal Tometi, used the hashtag to bring visibility to multiple accounts of anti-Black racism across the globe and to organize the resulting outrage. This was not just an online movement; it also coincided with protests in the streets. The hashtag created a container to archive the state-sanctioned, white supremacist, and vigilante violence disproportionately wielded upon Black bodies.

Black Lives Matter is also a chapter-based and member-led organization that works to build local power and structures of community accountability that do not rely on policing. BLM organized the Black Lives Matter Freedom ride to Ferguson, Missouri, a residential suburb of St. Louis, when protests broke out after 18-year-old Michael Brown was killed by a white Ferguson police officer in 2014. Black Lives Matter can be said to be following the model of civil rights organizer Ella Baker by having many leaders and thereby challenging the one charismatic male leadership model that both spurred and stifled the civil rights and Black Power movements between the 1950s and 1970s.

Black Lives Matter is one of the many Black-led organizations that is a part of a larger coalition, the Movement for Black Lives (M4BL). The Movement for Black Lives is a national and international political and ideological movement that focuses on the liberation of Black people in an anti-Black world. This is an intersectional Black feminist movement that is abolitionist and radical at its core, particularly in the way the movement highlights the voices of Black queer people, especially Black trans people. It separates itself from past Black social movements in its challenge to a charismatic patriarchal leadership model. The Movement for Black Lives created a kind of coalition for the work that was already being done to combat anti-Blackness and white supremacy while it also opened a space for more freedom dreaming

work to develop. This freedom dreaming work has included a gender analysis that is both antipatriarchal and trans and queer inclusive.

Many organizers in the Movement for Black Lives iterate that #allblacklivesmatter. The intentional inclusion of queer and trans people is one of the qualities that makes this Black Power movement unique. It has been unapologetically trans supportive and not wed to a politics of respectability that would force certain people out of possible leadership roles because of their intersectional identities, like being Black and trans.

The Movement for Black Lives became a hub for Black organizations, like Black Lives Matter, to build relationships where they could address the dynamic organizing work happening across the United States and abroad that focuses on disparities in Black communities that, for example, make Black life expectancy much lower than in white communities. The purpose of this hub is to create space for dialogue across organizations and to co-create a shared political, cultural, and ideological strategy that demands anti-Black racism be made center stage.

This is a movement of aspiration, based on a model of transformative justice and abolitionist feminism. It operates from the belief that change is possible if we work toward decolonization of not just the world around us but also of ourselves. While much of the movement's activism that has been captured through video screens shows chants, marches, and demonstrations, the work also includes radical self-care and consciousness raising, particularly around the ways in which addressing gender-based violence is essential to combating anti-Blackness.

The Movement for Black Lives strives toward an intersectional politic that can hold all Black people, especially women, trans, queer, disabled, and undocumented people. While M4BL raises awareness about heterosexual cis Black men who have been the victims of anti-Black racism, they are clear in bringing attention to the ways in which Black trans people are often more susceptible to premature death because of transphobia, both within and outside Black communities.

#BlackLivesMatter intersected with the rise of a boisterous gender justice movement, so it is not surprising that a hashtag like #BlackTransLivesMatter would also enter the public sphere at the same time. M4BL also coincided with the heightened visibility of Black trans people, especially trans women, in film and television. The movement also worked to highlight not just the deaths of cis Black men but also those of Black women and trans and gender-nonconforming people.

The Movement for Black Lives is also a movement for trans lives. Their work is to engage the populations most at risk for premature death. Black trans people are not only subject to state-sanctioned and vigilante violence, but they are also vulnerable to the rampant transphobia within and outside of Black communities that leads, for example, to higher rates of psychological distress and more frequent suicide attempts for trans people of color.

In 2020, protests and civil unrest swept the United States after George Floyd was murdered by a white police officer, who forced his knee on Floyd's neck for almost 9 minutes. But it was not just George Floyd; at the same time, there was also Tony McDade, a Black trans man shot by police, and Iyanna Dior, a Black trans woman, who was brutally attacked by a group of cis Black men. This attack moved many Black trans activists to remind the world that when it comes to Black trans lives mattering, it is not just about overpolicing, lack of employment, and houselessness. It is also about pervasive transphobia and the ensuing transphobic violence that must be understood within a framework of anti-Blackness.

Black People

As an academic field, Trans Studies is relatively new, and the specific focus on and mention of Black people in Trans Studies is even more recent. This entry will address both the presence of Black people and Blackness in the field of Trans Studies, as well as how thinking about Blackness's relationship to gender nonconformity necessarily alters our understanding of gender nonconformity as such, its racialized baggage, and its attending oversights. In short, the operative question becomes, How have Blackness and Black people raised a critique of gender and Trans Studies such that gender and Trans Studies must fundamentally revise their conditions of emergence?

As with many, although not all, academic disciplines in the humanities, Trans Studies initially did not consider the impact of race, specifically Blackness, on conceptions of gender. Much of the early scholarship in what might be understood as an inchoate Trans Studies was written by cis people in medical professions. This scholarship is epitomized by psychologist John Money and his team at Johns Hopkins University in the 1950s. Not only was this early era of the field deeply pathologizing of trans identity, negatively medicalizing deviations from cisnormative assumptions of proper gendered personhood, but it also did not consider how the history of racialization necessarily troubled what "gender" is and what it might mean for different people, cultures, and times.

Blackness and Black people were largely absent from the early era of scholarship concerning trans lives. This absence is conspicuous considering a number of factors. First, Black trans women and other women of color were on the frontlines of key moments in trans history, especially the Stonewall Riots, which is heralded as the defining moment of gay liberation but is also, rightly, a watershed moment in trans history. Although the actual events are contested and media representations have been all but uniform, it is likely that the person who "threw the first brick," as it were, that precipitated Stonewall was Black butch lesbian and drag king Stormé DeLarverie. DeLarverie, however, has denied starting the riots, deeming it more important to say simply that the riots happened and that the queer and trans community took collective action. This understanding places the convergence of Blackness and gender nonconformity inextricably at the foundation of queer and trans activism and crucially does not fall prey to narrative tropes of movements starting from a specific person. Bringing Blackness to bear on trans historiography highlights the collective and the coalitional, rather than the individualistic.

Second, to holistically capture how trans people experience the world, one must take into consideration the experiences of Black trans people. Far from simply acknowledging that Black trans people exist too or that Trans Studies has been haunted by the assumption of whiteness—both of which are, indeed, mostly true—the assertion here is that the intersections of Blackness and transness allow for different insights into transness and gender. For example, the experiences and knowledges of trans elders like Marsha "Pay It No Mind" Johnson and Miss Major, or the younger generation of Black trans activists like Laverne Cox (who graced the cover of *Time* magazine with the headline "The Transgender Tipping Point"), Janet Mock, Kortney Ziegler, and CeCe McDonald, need to be heeded. Their experiences highlight the intensification of violence at the nexus of Blackness *and* gender nonconformity (of note is how most trans people murdered are trans women *of color,* which is often elided in popular discourse); the intimate link between Blackness, transness, and incarceration (see, for example, the case of CeCe McDonald); and, as is detailed more below, how Blackness necessarily promotes a troubling of gender—or, in other words, Blackness might always already be tied up with transness.

To that end, third, and more theoretically inflected, if Trans Studies is concerned with how gender is and has been troubled, interrogated, and done differently, central to this endeavor is the history of Blackness and Black people. From the work of Hortense Spillers to C. Riley Snorton to Kai M. Green to Che Gossett, one can see how Blackness must be considered in close relationship to the gender troubling that *trans* is meant to name. This is because gender has been constructed through whiteness, which is to say that to be "properly" gendered, one must approximate whiteness, as those who are permitted to inhabit a seamless gender within the binary are those understood as

proximal to whiteness. In other words, being seamlessly a "man" or a "woman" was historically available only to those who also occupied a status as white.

To support this claim, Hortense Spillers considers the transatlantic slave trade, in which captive Black subjects were taken in as quantities rather than as gendered subjects, because their Blackness was seen as disqualifying them from the protections and expectations of gender (e.g., Black women being disallowed the sexual privacy and respect constitutive of white femininity; labor being defined not by gender roles but capacity [enslaved workers were described as full-hands, 3/4-hands, 1/2-hands, etc.]). Relatedly, Che Gossett turns to the era of Jim and Jane Crow, in which bathroom segregation, with its signs of "Men," "Women," and "Colored," revealed how gender was collapsed and nondistinct when proximal to Blackness (or "coloredness"). A final example is provided by Shaadi Devereaux, who notes that, even in the contemporary era, Black women are jettisoned from cis womanhood, always viewed as "drag performers"—approximating, but never fully inhabiting, proper femininity.

The most impactful work to date on the intersections of Blackness and transness is C. Riley Snorton's *Black on Both Sides: A Racial History of Trans Identity.* Published in 2017 and winner of the Lambda Literary Award for transgender nonfiction and the Sylvia Rivera Award in transgender studies from the Center for Lesbian and Gay Studies (among numerous other recognitions), Snorton's book uses archival materials from the 19th and 20th centuries to uncover the interrelation between Blackness and transness. Through these documents, which include legal, literary, medical, and historical sources, Snorton reveals that slavery and the reproduction of racialized gender rest at the foundation of a conception of gender mutability. In short, Snorton shows how Blackness and its placement outside the symbolics of binary gender cohesion serve as the condition for transness or gender changeability.

Snorton's book is part of a critical and growing mass of texts that highlight the specific intersection of Blackness and Trans Studies. Others in this cohort include the academic monographs *Trap Door: Trans Cultural Production and the Politics of Visibility* and *Captive Genders: Trans Embodiment and the Prison Industrial Complex;* "The Issue of Blackness," special issue of the journal *TSQ: Transgender Studies Quarterly;* and Daniel Black's novel *Perfect Peace.* These works have initiated a shift in Trans Studies that takes seriously the necessary gender trouble that Blackness promotes. While valid and necessary recovery projects have been undertaken (i.e., to "recover" forgotten or lost historical figures who may have been trans), the aforementioned work is doing more than recovering. That which might fall under the heading Black Trans Studies is a move to think differently about the past and to cultivate a way of thinking that allows forgotten or suppressed subjects to emerge differently. Outside of medical diagnostics and traditional notions of trans identity, thinking with the nexus of Blackness and transness provides alternative definitions of being trans. Not only is this occurring in academic spaces with, for example, scholars excavating the trans masculinity of historical civil rights figure Pauli Murray, but it is also occurring outside the academy with, for example, remembering the events of the Stonewall uprising differently or Tourmaline's vital (and often uncredited) filmic work on Sylvia Rivera and Marsha P. Johnson.

Quantitative work on how Black trans people experience life today indicates that there is a complex interplay between Black trans identity and inhabiting the social and political world. Studies show, for example, that Black trans people must navigate issues like passing, realness, authenticity, and transnormativity (i.e., the narrow ways that trans identity is seen as "valid" or not). These themes are confining for many Black trans people in terms of needing to "measure up" to various gendered standards, with failure to do so resulting in invalidation. But, at the same time, they are emancipatory in terms of allowing for avenues through which to tinker, revise, and creatively deploy new modes of gendered identity through old modes.

Various studies indicate that trans women of color, and Black trans women specifically, are disproportionately affected by negative health and economic outcomes such as suicidality, HIV, residential instability, unemployment, and survival sex work. Facing higher rates of institutional violence, discrimination, and harassment than other trans people, including from spaces like the church,

schools, and the criminal justice system, Black trans women often rely even more on community support networks for sustenance and comfort. Other measures that would mitigate these harms, according to studies, include the use of trans-appropriate and trans-sensitive language, efforts to prevent physical and sexual assaults, and antidiscrimination policies.

Finally, it is necessary to make clear, albeit briefly, that Black trans life is not entirely reducible to disproportionate rates of harm and violence. This would troublingly define Black trans existence solely and exclusively in terms of an increased capacity for violation, negating the multifaceted nature of Black trans life. So, while Black trans people are subject to a greater level of violence, they also experience a vast array of support, communities, ball cultures, love, liberating experimentation with different ways of inhabiting gender, and, indeed, success. These elements are also important forces in Black trans life and must be acknowledged even in the midst of pervasive Black trans harm.

At present, Black trans people are in myriad fields and arenas of social life. Black trans singers like Shea Diamond, actors like Laverne Cox and Brian Michael Smith, writers and activists like Janet Mock and Monica Roberts, and athletes like Patricio Manuel are all part of a growing awareness and visibility of Black trans people. They are shifting the terrain of what is possible, who is given a seat at the table, and how we might develop new ways of forming society that are more inclusive of racialized gender difference. Situating Black people in Trans Studies is more than a recovery project; it foreshadows what must happen in order for a fundamental shift in the world to occur.

Body Image Disturbance and Eating Disorders

The concept of *body image* is used in a range of different academic disciplines, ranging from social to neurosciences, yet consensus on its definition is lacking. Most definitions share the notion that one's body image relates to one's physical appearance, the psychological attributes regarding one's physical appearance, and the social context in which one exists. Personal and societal norms of physical appearance, as well as psychological attributes, are largely gendered, and thus, body image is considered a key concept in the psychological well-being of trans individuals. Body image disturbances in trans individuals may be closely related to experienced gender incongruence or dysphoria or may be more generalized. A more generalized body image disturbance is often associated with poorer outcomes of gender-affirming medical treatments, as it is followed by disappointment and persistent maladaptive coping.

Disordered eating may be the result of severe body image disturbances or can be applied intentionally as a strategy to influence gendered body

development. In the first case, disordered eating can be the consequence of body dissatisfaction or little behavioral investment in physical health. In the second case, restrictive eating can be done with the intention to lose weight, in order to strive for feminine thinness or suppress gendered body characteristics (e.g., body curves or menstruation).

This entry discusses the cognitive, affective, and behavioral aspects of body image (disturbances) in trans individuals and provides a description of the clinical presentation of eating disorders and relationship with body image disturbances.

Body Image Disturbance

Body image is a multifaceted and complex psychological construct with multiple synonyms such as *body (dis)satisfaction, body esteem, body dysphoria* (or *euphoria*), and *weight (dis)satisfaction*. For this entry, *body image* will be defined as attitudes, experiences, and societal norms regarding one's physical appearance. Body image is unique in the fact that the concept recognizes that the body intersects with both internal beliefs as well as societal ideals, media communications, disciplining behavior, and so on. Broadly speaking, one could say that the psychological self can communicate concepts such as gender through physical appearance, clothes, and behavior, whereas society produces physical ideals, which are largely gender specific.

Dramatically affecting people's lives, body image issues have been recognized by the World Health Organization as one of the important concepts constituting an individual's quality of life. A positive body image is closely associated with feelings of self-esteem, competency, resilience, and favorable mental health.

Although the trans experience can greatly differ on an individual basis, data from clinical facilities providing gender-affirming care indicate that a substantial share of individuals experience *gender dysphoria* (i.e., psychological distress resulting from the incongruence between gender identity and aspects of [mostly gendered] physical appearance). Body image issues are often closely related to experienced gender dysphoria and are among the main motives for people to apply for gender-affirming medical treatments. Yet, body image issues do not necessarily have to relate to gender dysphoria but can be present when physical appearance does not meet one's own or societal standards or when experiencing rejection or discrimination. The following sections will further detail cognitive, affective, and behavioral aspects of body image disturbances in trans individuals.

Cognitive Aspects

Cognitive aspects of body image have been extensively studied and refer chiefly to thoughts and experiences related to physical appearance. On the most elementary level, neuroimaging research has observed that body representation in the brain differs between trans and cisgender (cis) individuals. Trans individuals show brain activity more typical for their experienced gender, rather than their assigned sex. Researchers have also observed that sensory brain circuits show lesser connectivity to emotional circuits, implying a disconnect between body registration and emotion.

The most well-known aspect of body image is body (dis)satisfaction. Many trans individuals, especially those applying for gender-affirming care, experience substantial body dissatisfaction. Whereas earlier theories mostly included dissatisfaction with primary gender markers, such as genitals and breasts, contemporary scholars highlight the importance of other body characteristics as well. The distinction is often made between the trans public and private body (image). The *private body* refers to primary sex characteristics important for personal congruence or sexuality, whereas the *public body* refers to socially visible body characteristics that are of importance for being gendered correctly, such as hair growth or pitch of voice. In this context, the concept of *passability* is often brought up. Passability refers to the individual's ability to pass (i.e., be viewed by others) as their experienced gender. Generally, trans individuals who pass to a greater degree show higher body satisfaction, and trans individuals themselves report more appreciation for body parts that pass more. However, it should be noted that the concept of passability is criticized on the grounds that it reinforces binary gender stereotypes and that, importantly, individuals with poor passability may nevertheless experience few body image issues due to successful coping and vice versa. Pubertal sex hormone exposure, especially to testosterone, leads

to irreversible gender-specific physical changes that affect passability and body image later in life. Next to genital dissatisfaction, trans women report highest dissatisfaction with body characteristics related to the effects of testosterone (e.g., male-typical baldness, low voice pitch, facial hair growth). While trans men generally experience the most dissatisfaction with breasts and hips, feminine characteristics can more easily be overridden by testosterone therapy, resulting in lower body satisfaction on average. Given the binary notion of passability, nonbinary individuals are generally less likely to pursue being passable. As a result, this group is subject to more discrimination owing to society's inability to easily gender them.

A less frequently studied cognitive aspect of body image includes body image schemas and beliefs. Body image schemas are fundamental beliefs about appearance, one's appearance in relation to the self (self-evaluative salience), and behavioral investments made in appearance (motivational salience). Body image schemas are thought to be closely related to (gender) identity, and developing positive schemas can be protective in maintaining positive mental health. In contrast, negative schemas can result in dysfunctional coping such as repeatedly seeking reassurance, avoidance, or disordered eating. Other body image–related beliefs that may affect mental health include experienced attractiveness to others (lower in trans individuals), appearance-related insecurity (higher in trans individuals), and weight preoccupation (not necessarily increased).

Affective Aspects

Affective aspects of body image include feelings and mood related to physical appearance. For trans individuals, severe body image issues resulting from the incongruence between identity and physique may result in gender dysphoria. Body image–related dysphoria feelings can be primarily individual and experienced when not meeting one's own physical standards or gender identity and can therefore be triggered by, for example, looking in the mirror. Additionally, body image–related dysphoria is also frequently experienced in social situations, specifically in situations when the body is exposed, being objectified, or being misgendered. Trans men, for example, report highest social dysphoria when others look at dissatisfactory body parts, when being naked with a partner, when being touched, and when being fitted for clothes in a shop. All in all, affective aspects of body image and gender dysphoria can greatly reduce experienced quality of life through decreased feelings of sufficiency as a man/woman, as a (sexual) partner, or feelings of self-worth. Nonbinary individuals often have to navigate their individual body image outside these male–female scripts.

It should be noted, however, that body or gender dysphoria highlights the negative affective aspects only, while at the same time, many trans individuals experience so-called *gender euphoria* (i.e., comfort, joy, or pride with one's gender). It is thought that more visibility of gender variance and social acceptance of diverse (gendered) physical appearances positively contributes to individual body image–related feelings.

Behavioral Aspects

Body image–related behavior is largely the result of coping with gender incongruence, social distress, and physical ideals. When experiencing body image issues, people can develop maladaptive coping behaviors, such as avoidance or developing eating disorders (elaborated below). Alternatively, individuals may develop or seek out other coping behaviors, such as exposure (e.g., coming out, engaging in social activities such as sex or sports) or peer-to-peer counseling, or may seek gender-affirming treatments or apply other types of body-modifying behavior (e.g., chest binding or grooming) to improve passability and to align their physique with their physical ideals. Decreased attention to one's body or health, as well as locker-room issues, contributes to lower sports participation of trans individuals prior to medical transition (although not all trans individuals medically transition). As a result, trans individuals more frequently suffer from being overweight and show lower levels of illness awareness. Similarly, trans individuals with body image issues engage less in romantic relationships and are less sexually active. When body image issues decrease (e.g., as the result of medical transition or affirming relationships), engagement in and enjoyment of sex usually improve. This again adds to feelings of attraction, resilience, and

exposure—all of which further improve one's body image.

Associated Factors and Targets of Intervention

Research has identified three primary factors associated with body image disturbances: (1) coexisting mental health issues, (2) gender-affirming interventions, and (3) social stressors. Regarding the first aspect, trans individuals with coexisting mental health issues such as anxiety or depression are more likely to experience more severe and generalized body image disturbances (i.e., beyond gendered body characteristics) and more frequently experience persisting body image problems after medical transition. Besides medical transition, individuals usually benefit from additional anxiety/depression treatments and affirmative counseling. Consistently, a large body of literature finds that medical transition (i.e., by hormones and/or surgery) significantly improves the body image of the vast majority of trans individuals; the gender-congruent body receives higher satisfaction, after which individuals socially participate more and experience more instances of affirmation and increased levels of self-esteem. Hormone therapy generally improves satisfaction with muscularity, body shape, voice, and hair, while improved satisfaction with genitalia/breasts is mostly experienced after surgery. Knowledge concerning social stressors and trans individuals' body image can be derived from studies dealing with the effects of societal physical ideals and minority stress. Similar to their cis counterparts, trans individuals can feel pressured by unrealistic societal standards for physical appearance (e.g., mesomorph body shape, thinness). Additionally, some of these standards may be even more difficult to achieve for trans individuals, given the influence of prior feminization/masculinization and the limitations of hormones and surgery. This situation can result in increasing experiences of *self-objectification* (i.e., seeing oneself as an object rather than a person) and body image disturbances. In many cases, trans individuals deviating from societal norms experience higher levels of *minority stress* (i.e., experienced stress resulting from being a minority group member) resulting from stigma and/or discrimination in day-to-day life.

Eating Disorders

Eating disorders are among the most lethal mental health problems and can be a sign of maladaptive coping with severe body image disturbances. Therefore, most of the risk factors of body image disturbances in trans individuals are also involved in developing eating disorders. As a result, the elevated levels of body image disturbances and stress related to (unrealistic) societal physical ideals put trans individuals, especially trans women, at risk of developing eating disorders. Additionally, eating disorders in trans individuals frequently develop more severely with coexisting self-harm or suicidality. The increase in eating disorders includes both bulimia nervosa (binge eating followed by purging) as well as anorexia nervosa (weight loss through purging, restrictive eating, and/or excessive exercising). In addition to nonspecific body image disturbances, trans-specific motives for (restrictive) disordered eating include striving for femininity through thinness, reducing unwanted sex-specific body curves, and stopping unwanted menstruation. It is therefore important to be aware that the underlying motives of disordered eating in trans individuals may be strong and closely related to experienced gender dysphoria.

Several studies have identified risk and protective factors in trans individuals. Risk factors include high body dissatisfaction, perfectionism, anxiety, and minority stress, while family connectedness and social support are seen as protective factors. Gender-affirming medical treatments generally alleviate both body image issues and disordered eating. Yet, although substantial knowledge is available on trans-specific body image disturbances and disordered eating, far less is known on the effectiveness of generic psychotherapeutic interventions (e.g., cognitive-behavior therapy) and what the effect will be of changing (gendered) physical ideals.

Body Size (Weight)

Body size (weight) is considered an important physical health indicator as well as a factor impacting mental well-being. Weight issues in trans individuals may be preexistent or develop upon initiation of hormone therapies. Both total body weight and fat distribution can change as a result of hormone therapy. Both over- and underweight individuals can experience limited access to gender-affirming care, which ultimately may prevent people from the ability to transition fully. This entry discusses body weight in trans individuals, with special focus on the occurrence and nature of weight issues, as well as the effects on physical and mental health and the implications this may have regarding access to gender-affirming care.

Body size and, specifically, body weight issues are known to be prevalent in different subgroups within the LGBTQ community. While the evidence on trans individuals' body size is relatively scant, some clinical and community sample studies provide information on trans individuals specifically.

Weight Issues

Weight issues are generally related to overall body weight, nutritional intake, and physical exercise problems. In both LGBTQ and (few) trans-specific studies, trans individuals score unfavorably when compared with their cisgender counterparts on all three of these domains. Often these issues originate during childhood and adolescence. In general, adolescence is considered an essential period in developing healthy dietary and physical activity habits, as well as body weight. For many trans individuals, this same period is characterized by distress resulting from unwanted hormonal developments or by going through medical transition.

Compared with cisgender (cis) individuals, trans individuals are two to four times more likely to be either underweight or overweight/obese. In line with this, trans individuals report both less variation in and consistency concerning food intake (e.g., they eat more fat-rich food; they more frequently skip meals). Additionally, more screen time and less sports engagement are observed within this population. Yet, it is important to note that physical activity and balanced nutritional intake are strongly related to socioeconomic status and that trans individuals frequently report a lower income and are more marginalized, making them prone to an unhealthier lifestyle.

Physical Health

The effects of overweight (BMI, or body mass index, 25–30 kg/m^2) and obesity (BMI > 30 kg/m^2) are well known and include cardiovascular disease, diabetes, cancer, and lowered life expectancy. There is a dose-dependency relationship, meaning that health risks are higher in individuals with a higher BMI. Exact numbers on the prevalence of over- and underweight in trans individuals differ per context and measurement methods, yet weight issues account for a substantial share of the health burden.

Hormone therapy as part of gender-affirming medical care influences both total body weight as well as fat distribution. Total body weight increases as a result of feminizing and masculinizing hormonal treatments. However, sex-specific changes are observed in body composition; feminizing hormones (estrogens and antiandrogens) increase body fat and lower muscle mass, whereas

masculinizing hormones (testosterone) lower body fat and increase muscle mass, all up to changes of 1 to 4 kilograms. As a result, body shape develops in a feminine- or masculine-typical direction, a development that can continue for years after initiation of hormones.

When an individual is underweight, the body may possess insufficient nutrients, including energy and vitamins/minerals, for a healthy metabolism. Physical health complications of (chronically) underweight persons include poor physical condition, weakened immune system, osteoporosis, and decreased fertility. As with obesity, being severely underweight is associated with decreased life expectancy.

Psychosocial Health

Weight issues in trans individuals are associated with multiple psychosocial factors. First, gender incongruence can lead to *body image* issues, avoidance of sports engagement (e.g., because of locker room issues) and maladaptive coping such as disordered eating. Being overweight can further, and independently of gender-related body dissatisfaction, induce body image problems. Paradoxically, being underweight is often motivated by reducing gender incongruence via striving for femininity through thinness, reducing body curves, and stopping menstruation. Alternatively, individuals with constructive adaptive coping experience lower body image issues through physical exercise, being in good physical condition, having affirming experiences, and developing increased self-esteem.

While individuals themselves can adapt positively to weight issues, the social environment greatly influences psychological health in trans individuals with weight issues. In addition to societal gender norms, individuals with weight issues can experience additional psychological stress as a result of deviating from societal body size norms. Notably, around 50% of trans adolescents experience weight teasing by peers and/or family members. This puts individuals at risk for poor mental health and substance use. Given the aforementioned issues, schools as well as parents can contribute to providing a safe climate where individuals feel emotionally supported, thereby contributing to positive eating and exercise behaviors.

Access to Medical Gender-Affirming Care

To many trans individuals experiencing *gender dysphoria,* receiving gender-affirming care is crucial to maintaining good mental health. Being overweight, however, is a serious barrier to accessing medical gender-affirming care. Due to the mild interaction that hormone therapy has with being overweight, routine physical and laboratory tests have proven to be sufficient. Yet, many clinics uphold BMI requirements for gender-affirming surgeries. Typically, the requirements for top surgery are less strict than those for bottom surgery. Although the quality of evidence is debatable, obesity has been linked to technical surgical difficulty, poorer tissue survival, more anesthetic complications, and poorer overall outcomes among trans people.

As a result, weight is one of the largest barriers to surgical care and a frequent topic during preoperative counseling. Given the complex background of weight issues in trans individuals and the limited resources some may have, self-monitored weight loss is generally insufficient in removing this barrier to surgery. Therefore, both prevention and guided weight loss programs are being advocated to secure access to gender-affirming surgery.

Bono, Chaz

Chaz Bono is an LGBTQIA+ activist, actor, and author whose transition from female to male in 2008 made him the most well-known U.S. trans man in the early 21st century. Bono's visibility has included extensive interviews, advocacy work, the *Becoming Chaz* documentary, appearing on *Dancing With the Stars,* and starring in the drama *American Horror Story*. This extensive coverage positioned Bono as the accessible face, name, and reference point for the public on trans male lives.

Childhood and Family

Bono was born on March 4, 1969, in Los Angeles, California, to Cher and Salvatore Phillip "Sonny" Bono. The only child of the singer-entertainer "it couple" who topped the pop charts with "I Got You Babe" in 1965, Bono was raised in the spotlight of family fame. Appearing weekly on *The Sonny and Cher Comedy Hour* from 1971 through 1974, his early childhood was both accessible and enthusiastically accessed by the public. Viewers were enamored of Sonny and Cher, an affection amplified by Bono's appearance at the end of each show. With its depiction of a youthful, joyous family, *The Sonny and Cher Comedy Hour* occupied an idyllic space within the U.S. imagination, which helped ensure that the public would remain interested in Bono's life.

Youth, Adolescence, and Coming Out as Lesbian

Bono's adolescent years were challenging. He had difficulties adjusting to Sonny and Cher's divorce and the ensuing custody arrangements, and struggles with his gender and sexuality added more anxiety. While Bono had been called a "tomboy" as a child for behaviors, styles of dress, and interests socially coded as masculine, puberty was accompanied by the expectation that girls "grow out of it." As this pressure increased, so did the sense of being different. Uninterested in demonstrating femininity and equally uninterested in engaging with boys, Bono had neither the words nor the context to understand what any or all of these feelings might mean. At 13, after seeing the film *Personal Best,* Bono started identifying as lesbian. He documented these formative years of struggle and growth in *Family Outing: A Guide to the Coming-Out Process for Gays, Lesbians, and Their Families*.

When he was 23 years old, Bono began a relationship with Joan Stephens, a friend of Cher's who had recently been diagnosed with cancer. They remained together for 2 years, until Stephens's death in 1994. Devastated by the loss, Bono used painkillers for the next 10 years, which he detailed in *The End of Innocence: A Memoir* (2002). In 1998, Bono was further devastated by the loss of his father, who died in a skiing accident. Although Sonny had been supportive of Bono, he had also been elected as a conservative congressional representative and cosponsored the Defense of Marriage Act (DOMA), which legally restricted the definition, rights, and protections of marriage to one man and one woman. Bono had campaigned against DOMA, as well as for the reelection of President Bill Clinton, and their political differences resulted in the two being estranged at the time of Sonny's death.

Coming Out as a Trans Man, Transition, and Trans Visibility

In 2009, Bono publicly announced that he was a trans man and wanted to be referred to as Chaz Salvatore Bono, a name he took to honor his father. He characterized his previous lesbian identity as a result of mistaking his sexual orientation (i.e., being attracted to women) with his gender identity (i.e., being a heterosexual man).

Within 2 years of coming out as a trans man, Bono wrote the *New York Times* bestselling book *Transition: The Story of How I Became a Man* (2011). Known for its down-to-earth, straightforward approach, the memoir is a candid exploration of the physical, emotional, and psychological

effects of Bono's medical transition, his relationship with Cher, and the difficulties of navigating family dynamics within the public eye. A year later, Bono was the subject of the documentary *Becoming Chaz,* which further chronicled his transition, including his reconstructive chest surgery. Rather than a sensationalist approach, the film provided an accessible, real-life account of a trans man's life. It was the kind of openness from a celebrity that appealed to viewers; the movie was shown on the Oprah Winfrey Network, which led to it being nominated for three primetime Emmy awards and winning the GLAAD Media Award for Outstanding Documentary.

Bono is best known in recent years for participating on the 13th season of *Dancing With the Stars* in 2011, which made him the first trans man to be featured on a major television show in a role that did not relate to him being trans. Nevertheless, the response to his appearance largely centered on his gender, rather than his dancing. Social conservatives urged a boycott of the show, stating that the image of a trans man would confuse and harm children. Others, including the judges, criticized him for his weight and mannerisms. Bono responded by calling attention to the bias behind the attacks and by noting the value to viewers of being able to see a different kind of man on TV. By dancing his way into people's homes, Bono shaped a dialogue about modern manhood, LGBTQIA+ equity, bodies, and the power of media representation.

Bono has also had a small number of acting roles playing non-trans characters. He has indicated that he avoids trans parts for fear of being typecast. He most notably appeared in 2017 on the seventh season of *American Horror Story* as a fervent Donald Trump supporter.

A long-time believer in "visibility equals equality" as both a personal and political strategy, Bono has worked as a writer for *The Advocate* and has served as a national spokesperson for the Human Rights Campaign and as the Entertainment Media Director for GLAAD. In each endeavor, he foregrounded the fight for equal rights for the LGBTQIA+ community, worked toward political and legal advancement, and encouraged patience and connection with family and loved ones. In recognition of his work, Bono received GLAAD's Stephen F. Kolzak Award in 2012, which honors an openly LGBTQ person in the entertainment industry who has made a significant difference in improving the climate for LGBTQ people.

Bornstein, Kate

Katherine Vandam "Kate" Bornstein is a writer, performer, and early influencer of the trans liberation movement in North America. Through her artistic contributions, Bornstein advanced trans awareness and the popular understanding of gender fluidity. Her best-known work is the 1994 book *Gender Outlaw: On Men, Women, and the Rest of Us,* which was also the title she used for talks on college campuses across North America for the following two decades. Bornstein's work stood as a counterpoint to early narratives of trans respectability politics, as she spoke and wrote openly about her queer identity, her participation in the BDSM community, her eating disorder, her involvement with Scientology and subsequent exploration of Buddhism, and her unmistakably queer look and politics. Her career has been marked by multiple books that were considered controversial when they appeared but that were later understood as having been groundbreaking.

Bornstein was born on March 15, 1948, in Neptune City, New Jersey. Working primarily in New York City and Seattle, Washington, and using her theater training from Brown University (graduated 1969), Bornstein began publicly

exploring her trans identity and the nature of gender in the early 1990s with a triptych of solo performances: *Hidden: A Gender, The Opposite Sex Is Neither,* and *Virtually Yours*. In these works, she challenged the notion of a gender binary and pointed to the fluidity of gender, recognizing that gender represents a multifaceted core "self" that is shaped by external forces and expressed in relation to others.

In the 15 years that followed, Bornstein contributed substantially to both popular and academic conversations about gender identity and trans liberation, one of the few people to work comfortably in both arenas. In 1998, Bornstein wrote *My Gender Workbook: How to Become a Real Man, a Real Woman, the Real You, or Something Else Entirely* using exercises that she had developed for speaking at colleges and to community groups and addressing the questions that she commonly received from audiences. *My Gender Workbook* was unique for its thoughtful but humorous look at the construction of gender and for its inclusive approach, which allowed people of all genders to consider their own participation in gendered systems. In 2010, she coedited *Gender Outlaws: The Next Generation* with S. Bear Bergman as an update to her book *Gender Outlaw,* collecting a multigenerational and diverse group of writers whose ideas the pair felt represented "a quantum leap forward" in thinking about gender identity.

Bornstein premiered her first and only play written for other actors, *Strangers in Paradox,* in 1998 at the Theatre Rhinoceros in San Francisco and collaborated with her partner, performer, and sexuality educator, Barbara Carrellas, on *Too Tall Blondes in Love* for the stage, which toured nationally during the early 2000s. These plays were continuations of Bornstein's earlier work about the nature of identity and the concepts of community and "sanity." *Strangers in Paradox* in particular explored, through metaphor, the idea that, for centuries, trans people were generally considered by Western medicine to be dangerously mentally ill.

Moving beyond strictly gender-related topics, Bornstein cowrote the adventure novel *Nearly Roadkill* in 1996 with Caitlin Sullivan; its themes of ever-changing identities in cyberspace and government intervention presaged the "identity wars" of the 2000s and the rise of state and commercial surveillance of the Internet. In 2006, Bornstein published *Hello Cruel World: 101 Alternatives to Suicide for Teens, Freaks, and Other Outlaws,* a book that provides options for people in distress other than ending their lives. It relies on a harm reduction model of suicide prevention and was controversial (and roundly condemned by some people) for encouraging readers to do anything that they thought would help, except suicide, which could include drug use and nonsuicidal self-injury. At book readings, she promised audience members that she would do their time in hell for them if they would stay alive and distributed "Get Out of Hell Free" art modeled on Monopoly's "Get Out of Jail Free" cards. Her one rule: "Don't be mean."

In 2012, Bornstein published her memoir, *A Queer and Pleasant Danger,* which detailed her coming-out processes, her relationships with her family, her work as an artist and educator, and her experiences in queer and BDSM communities. The book was adapted into an award-winning film by director Sam Feder, which was screened widely on the queer film festival circuit.

After being diagnosed with lung cancer in 2013, Bornstein spent a few years focusing on her health. She also further worked on her "quantum theory of gender," exploring the idea that gender, like light or time, exists on multiple axes and must be viewed on all of them simultaneously to be truly understood. In recent years, she appeared on the popular reality television show *I Am Cait,* which focused on Caitlyn Jenner's gender transition process, and on Broadway in Young Jean Lee's play *Straight White Men*. Through these roles, she continued to complicate people's understanding of the nature of gender.

A consistently controversial figure, who is frequently described as "flamboyant" because of her queer-coded, high-femme gender presentation, Bornstein has been an important contributor to contemporary conversations about gender identity and trans liberation. Her approachable writing and performance-driven educational style have encouraged audiences not only to become more supportive of trans people but also to examine the concepts of identity and the systems of gender. In continuing to assail the dichotomies of self/other, true/false, and good/bad, in addition to man/woman, Bornstein has capitalized on the initial

attention she received as a "transgender curiosity" to propose radically new and more inclusive lenses for understanding ourselves.

Boylan, Jennifer Finney

Jennifer Finney Boylan is a U.S. trans novelist, memoirist, professor of English, and leading activist for greater and more positive visibility of trans people in the media.

Boylan was born on June 22, 1958, in Valley Forge, Pennsylvania. She graduated from the Haverford School, a private all-boys preparatory school in Haverford, Pennsylvania, in 1976. After graduating from Wesleyan University with a bachelor's degree in English in 1980, she briefly worked alongside comedy legends like John Belushi, Dan Aykroyd, Gilda Radner, Lorne Michaels, Harold Ramis, and Michael O'Donoghue at the magazine *The American Bystander,* which folded after a single issue in 1982. After this abortive career in humorist periodicals, she went back to school and earned an MA in fine arts from Johns Hopkins University in 1986. She began teaching at Colby College in 1988, marrying Deirdre Boylan (nee Finney) in the same year.

Prior to coming out as trans, Boylan had published a number of novels. During the 1990s, she wrote three adult novels (*The Planets* in 1991, *The Constellations* in 1994, and *Getting In* in 1998) and four novels for young adults under the pseudonym Jonah Black.

She began medically transitioning from male to female in 2000 and wrote about her transition in the autobiographical memoir *She's Not There: A Life in Two Genders,* which was published in 2003. The book was a series of vignettes of her life with a focus on crucial moments related to her gender dysphoria, marriage, children, and transition. *She's Not There* represented a radical departure from previous works about trans people: It showed a marriage and relationships with her children enduring posttransition and also focused on the parts of her story she wanted to tell, rather than the parts that the public is usually presented with.

Boylan made four appearances on *The Oprah Winfrey Show* after the publication of *She's Not There,* including ones with her wife and two children. This was the first time that a trans person was presented as normal, pleasant, and human in such an influential public forum. These appearances helped vault her into the public consciousness, as well as onto the *New York Times'* Bestseller List, making her the first openly trans author to achieve that distinction.

She also made TV appearances on *Live With Larry King,* the *Today Show,* the *Barbara Walters Special,* NPR's *Marketplace,* and *Talk of the Nation*. She has been the subject of documentaries on CBS News's *48 Hours* and the *History Channel* and has been featured on numerous news programs. In 2005, Will Forte did an impersonation of her on *Saturday Night Live,* which Boylan described as "the highlight of my literary career."

Boylan has continued to have a very significant video media presence in recent years. She was a consultant and cast member on Caitlyn Jenner's reality TV series, *I Am Cait,* from 2015 to 2016. She appeared on the show as Jenner's friend, mentor, and trans community elder. She has continued to appear on news shows, like *MTV News, 20/20,* and *ABC News and World Report,* and to be featured in mainstream press outlets, such as the *New Yorker, Washington Post, U.S. News and World Report,* and *Entertainment Weekly*.

Boylan continued teaching at Colby College after becoming a public figure. She was named professor of the year in 2000, co-chaired the English Department between 2003 and 2005, and did two stints as director of the creative writing program. When she left Colby in 2014 after 25 years, she described her time there as "a model of what a successful transition could look like." In 2014, she became the inaugural Anna Quindlen Writer in Residence and Professor of English at Barnard College of Columbia University.

Since 2003, she has had a very productive writing career. Her nonfiction titles include *Stuck in the Middle With You: Parenthood in Two Genders* (2013), *I'm Looking Through You: Growing Up Haunted* (2008), *Good Boy: A Life in Seven Dogs* (2020), and a 10th anniversary edition *of She's Not There* (2013). Her fiction credits since 2000 include the novel *Long Black Veil* (2017), the novella *I'll Give You Something to Cry About* (2014), and the *Falcon Quinn* young adult antibullying novels. Her essays have been included in over 20 anthologies, and she wrote the introduction to the groundbreaking work on trans lives written for a trans audience, *Trans Bodies, Trans Selves* (2014).

In 2007, she became a contributing opinion writer for the *New York Times,* producing a regular op-ed column on a wide variety of topics. She is the only trans person whose work has appeared on a regular basis in a major U.S. newspaper. She primarily writes about LGBTQIA+ issues, and trans issues in particular, but has the ability to cover anything that interests her.

Boylan's rise to public prominence has also allowed her to assume a leadership role within the trans and larger LGBTQIA+ communities. She was named to the GLAAD (known as the Gay and Lesbian Alliance Against Defamation until 2013) board of directors in 2011. She became one of the co-chairs of the board in 2013 and served in that capacity until 2018, becoming the first trans person to be its board chair. In 2011, when Boylan joined GLAAD, trans issues barely registered on the organization's radar; by the time she left, a much larger portion of its work was devoted to trans issues. It was during her tenure that GLAAD dropped its old name in order to be more inclusive of trans people and their struggles.

Boylan also served on the board of the Kinsey Institute for Research on Sex, Gender, and Reproduction from 2012 to 2016. She is on the board of PEN America, which advocates for human rights and the free expression of ideas in literature, and on the Lambda Literary Leadership Council.

Her books, her appearances on Oprah and other TV programs, and her work at GLAAD have helped lead to much greater media visibility for trans people and increasing support for trans rights.

C

Campus Policies/Campus Climate

Even though more and more college students are coming out as trans and often demanding that institutions do more to address their needs, higher education remains a largely hostile environment for trans students, especially those who do not conform to a gender binary and those who possess multiple minoritized identities (e.g., trans female students, trans students of color, trans students with disabilities). Studies have shown that trans students have more negative perceptions of curricular and cocurricular inclusivity, classroom climate, and the overall climate on their campuses than do cis students, including cis LGBQ+ students, and have a significantly lower sense of belonging within their college communities. Trans students commonly report discrimination in campus restrooms, housing, and counseling and health centers; institutional and individual misgendering; and verbal, physical, and sexual assault.

Lack of College Support

While hundreds of colleges implemented some trans-supportive policies and practices in the 2000s and 2010s, most institutions still offer little or no support to their trans students. Moreover, even the colleges that have taken steps to be more inclusive of and welcoming to trans students have a long way to go before they truly are. For example, in considering the experiences of trans students at two large, midwestern public universities that have implemented some trans-supportive policies and practices, education researcher Brent Bilodeau found that genderism—that is, the societal, institutional, and individuals beliefs and practices that assume that there are only two genders, that they are opposites of each other, and that they are determined by one's sex assignment at birth or by specific sex characteristics—still permeated every aspect of life on these campuses, including in classrooms, campus employment and career planning, student organizations and communities, and campus facilities. The nonbinary trans students in the study had an especially difficult time finding campus support, as the institutions remained firmly entrenched in a gender system that assumes that students are either male or female. It is noteworthy that these colleges had made some progress in recognizing and addressing the needs of trans students; institutions that have done little or nothing to support their trans students are presumably even more toxic environments.

Campus Restrooms and Housing

Discussions about the needs of trans people are often reduced to the issue of restrooms, with trans-misogynists arguing that the passage of trans rights laws will lead to individuals who are not women—cis men pretending to be women—and individuals whom they see as not "really" women—trans women—using women's restrooms. That said, restroom access is a critical concern for many trans people because they often experience harassment

and discrimination in trying to use women's or men's rooms, and they cannot reasonably hold a job or attend school if they are constantly worrying about having a place to pee in peace. In the 2015 United States Transgender Survey, the largest study to date of trans people in the country, more than a quarter of the respondents reported that they were denied access to a restroom, had their presence in a restroom challenged, and/or were verbally, physically, or sexually assaulted in a restroom in the previous year. Because of such experiences or a fear of them, a majority indicated that they sometimes or often avoided using a restroom. They "held it," which ultimately led some to develop urinary tract or kidney-related problems, and limited what they drank and ate to prevent needing to go to a restroom, which can likewise have negative long-term health effects.

Restroom access is also an extremely important issue for trans college students. Research indicates that many trans students experience harassment when they seek to use gendered campus restrooms, such as being stared at, questioned about their gender, told they are in the wrong facility, or ordered to leave. In the National Transgender Discrimination Survey, which was conducted in 2008–2009, about a quarter of those who had attended college stated that they were not allowed to use the appropriate bathroom facility on campus at some point because of their gender identity or expression.

Because of the threat of discrimination in gendered restrooms, many trans students will use only gender-inclusive facilities, but most colleges fail to provide enough of them. Surveying more than 500 undergraduate and graduate trans students, Abbie Goldberg, Genny Beemyn, and JuliAnna Smith found that the respondents rated having gender-inclusive bathrooms in most campus buildings as the most important trans-inclusive practice among a list of 17 different trans-supportive policies and practices. But only 45% of the participants indicated that their college had taken this step. In a study by Beemyn, which involved more than a hundred nonbinary trans students, a majority of the interviewees stated that what most made them feel unsupported by their colleges was a lack of gender-inclusive restrooms. Many of the students were able to indicate the exact location of all of the gender-inclusive facilities on their campus, because these were the only restrooms that they felt safe and comfortable using, and their college had so few of them. Moreover, the gender-inclusive restrooms that did exist were not always well marked and in convenient locations. Some of the students reported that they made sure to go to the bathroom before they left for classes and planned their day so that they could get back home in time to avoid needing to use gendered facilities, which caused them tremendous stress and personal discomfort.

As with restrooms, having a safe place to live is a basic need for trans students that is often not met by colleges. Many trans students report being assigned housing and roommates based on their assigned sex, rather than their gender identity; not having access to a gender-inclusive or a single-room housing option; having to use the "wrong" gendered bathroom in a residence hall; and being harassed by other residents without much recourse. For example, in the study by Goldberg and colleagues, less than half of the participants stated that their college enabled trans students to be housed in keeping with their gender identity/expression, and in the National Transgender Discrimination Survey, about one fifth of the respondents who sought to live on campus said that they were denied gender-appropriate housing.

By failing to provide gender-inclusive restrooms and housing options, institutions not only discriminate against trans students and expose them to potential harassment but also may be negatively affecting their mental and physical well-being in the long term. Using data from the National Transgender Discrimination Survey, social work researcher Kristie Seelman discovered that individuals who had been denied access to a campus restroom because of being trans were 1.45 times more likely to have attempted suicide at some point in their lives than those who were not denied access. Those who had been denied access to gender-appropriate campus housing because of being trans were 1.64 times more likely to have attempted suicide. The survey did not ask when the participants had attempted suicide, so access discrimination cannot be said to have caused suicidality, but these findings should still give college administrators pause. Institutions that do not have written trans-supportive policies and practices and that do not actively ensure that these

measures are followed risk causing irreparable harm to their trans students.

Mental and Physical Health Care

Along with higher rates of suicidal ideation and attempted suicide, trans students are more likely than their cis counterparts to experience negative mental and physical health outcomes because of the effects of discrimination, including anxiety, depression, posttraumatic stress disorder, anorexia, bulimia, phobias, and substance abuse/addiction. As a result, many trans students need and seek out mental health supports. For example, in a national study of incoming college students, nearly three fourths of the trans students indicated that they would likely pursue counseling at their institution, compared with less than half of the overall sample. At the same time, trans students who are medically transitioning often want or are required to have therapy before they are able to obtain a prescription for hormones or undergo gender-affirming surgeries. Having access to hormones is especially important for trans students who do not have families that support their transitions, as they had to wait until they were legally adults to begin the process.

But while trans students in general are more in need of counseling than are their cis peers, they commonly struggle to find campus therapists who are knowledgeable about and sensitive to their experiences. Trans students report that they are often placed in the uncomfortable position of having to educate mental health professionals about trans people and being asked inappropriate questions about their bodies. Nonbinary trans students are especially likely to encounter therapists who do not understand their identities; many indicate that mental health professionals expect them to want to medically transition, dismiss them or take them less seriously because they do not fit into a gender binary, and fail to respect their use of nonbinary pronouns, which means that they are regularly misgendered.

Similarly, trans students who seek services from campus health centers also often report a lack of competent care. In addition to commonly having to educate their providers and being misgendered and deadnamed (i.e., being referred to by their name assigned at birth, rather than their chosen name), they are frequently unable to receive transition-related health care and are sometimes denied health care altogether. Although an increasing number of colleges, including the school systems of the University of California, the University of Texas, the University of Minnesota, and the University of Michigan, are covering hormones and gender-affirming surgeries under student health insurance, the vast majority of institutions offer no support for transitioning students.

Individual and Institutional Misgendering

The frequent misgendering of trans students is not limited to campus counseling and health centers. In Beemyn's study of nonbinary trans students, their biggest complaint about their colleges, after the lack of gender-inclusive restrooms, was being misgendered in classes because there was not a way for them to indicate the name and pronouns they go by on course rosters, and faculty members did not ask them to indicate their name and pronouns at the beginning of courses. Education researcher Eleanor Finger similarly found that a mismatch between their chosen name and their legal name on course rosters and other institutional records was one of the most stressful situations encountered by the trans students she surveyed. Students were placed in the awkward position of having to come out as trans to faculty members whom they did not know before their first class to prevent being outed, if the instructor read the roster aloud, and to avoid possibly being referred to by the wrong pronouns. Many trans students are reluctant to approach professors about their name and pronouns, not knowing how their instructors will react, so they endure being misnamed and misgendered in their classes, even though this often makes them feel invisible and marginalized.

Nonbinary trans students are more likely to experience misgendering from both faculty and other students because, operating from a gender binary framework, many cis people automatically refer to them as "she/her" or "he/him." For example, in a study of trans grad students, psychologist Abbie Goldberg found that 44% of the nonbinary respondents stated that they were misgendered often by faculty members, and 45% indicated that they were often misgendered by other students.

Among the binary trans graduate students, the figures were 8% and 4%, respectively, with more than half saying that they were never misgendered. Similarly, sociologist Tre Wentling found that, among more than 500 trans students, only 15% of nonbinary students reported that their instructors always used the appropriate pronouns, compared with 63% of binary students. The nonbinary individuals assigned female at birth and the trans men who attend women's colleges are even more likely to experience misgendering by others because of the institutional assumption that all of the students identify as female and go by "she/her."

To limit being misgendered, trans students rate having the ability to change their name on campus records, including ID cards and course rosters, without a legal name change as one of the most important trans-supportive campus policies, but a majority of the students in the study by Goldberg and colleagues said that their college did not offer this option. In fact, less than 10% of all colleges do so, and even fewer give students the ability to indicate their pronouns on course rosters. Enabling students to have a chosen name and their pronouns on nonlegal campus records and documents is permissible in all states and is possible in all major student information software systems with little expense. Thus, an institution that wants to be trans supportive has no legitimate reason not to enact such policies so that trans students are not forced to be invisible by being misgendered or to be hypervisible by being outed.

Negative Campus Climates

Classroom Invalidations

Of course, indicating a chosen name and pronouns on course rosters, or coming out as trans to a faculty member in the absence of this option, does not ensure that the faculty member or other students in the class will respect how a trans student identifies. Many trans students, especially nonbinary trans students, have described incidents where a faculty member purposely addressed them by their deadname or the wrong pronouns. Even graduate students, who typically have a closer relationship with faculty members than undergraduates, commonly report being misgendered and misnamed. More than a quarter of the grad students surveyed by Goldberg stated that, even though they had asked the professors in their program to use the appropriate pronouns and name, the faculty members continued to misgender and misname them, as well as used cisnormative language in their classes, such as referring to the students as "ladies and gentlemen."

The frequent invalidation of their gender identities by professors contributes to gender-nonconforming students perceiving the classroom climate as more negative than gender-conforming students. All five of the trans students interviewed by education researcher Jonathan Pryor, for example, described feeling disrespected and marginalized in their classes by both faculty and other students. According to participants, their professors had little understanding of how to be supportive of trans students, and some reinforced a hostile, cisgenderist classroom environment by refusing to use the names and pronouns requested by students and by making anti-trans remarks. Participants also shared how some cis students similarly did not respect the gender identities of their trans classmates and made harassing comments. It is noteworthy that the trans students in Pryor's study experienced this negative classroom climate despite having taken steps to minimize mistreatment, such as by seeking to take large classes, where they would not be called on and potentially misgendered by professors, and by avoiding online courses, which often require the use of a student's legal name, and courses in STEM fields, which they believed had instructors and students who were more antagonistic toward trans people. The extent to which cisnormativity pervades academia is evident in that some trans students reported being misgendered in the presumably most supportive classroom context—small classes in Women's and Gender Studies.

Harassment

Outside of the classroom, trans students also encounter a chilly if not hostile campus climate. Among the respondents to the U.S. Transgender Survey who had attended college or vocational school and who indicated that people at their institution thought or knew they were trans, nearly one quarter stated that they were verbally, physically, or sexually harassed while they were students. The participants who identified as

American Indian, Black, and Middle Eastern were even more likely to report having experienced campus harassment. In the *2010 State of Higher Education for LGBT People,* the respondents were asked whether they had observed someone being intimidated or bullied because of their gender identity; answering in the affirmative were 38% of the gender-nonconforming participants, a third of the transmasculine participants, and more than a fifth of the transfeminine participants. More than three fourths of each group had also observed derogatory remarks being made about someone's gender identity.

Other research, which used data from more than 100 colleges, similarly found that trans students rated the climate on their campuses as more hostile, compared with their cis LGB and cis heterosexual peers. The trans-identified students indicated encountering more frequent harassment and discrimination, including from faculty and staff members, and had a lower sense of belonging within their campus communities. Because of harassment and discrimination, less than two thirds of trans students in another national study reported a sense of belonging on their campus, compared with 82% of cis students and about three fourths of LGBQ+ students.

Physical and Sexual Violence

In addition to frequently experiencing verbal harassment, trans students report extremely high rates of physical, sexual, and intimate partner violence. The largest study to date of sexual assault and misconduct on college campuses that explicitly included trans students was conducted in 2019 for the Association of American Universities (AAU) and involved 33 institutions and nearly 182,000 students, more than 3,000 (1.7%) of whom identified as a trans woman, trans man, nonbinary or genderqueer, questioning their gender identity, or a gender not listed (abbreviated as TGQN by the researchers). The study found that the TGQN undergraduate and graduate students reported the highest rates of experiencing harassing behavior, intimate partner violence, and stalking since starting college. For example, 65% of the TGQN undergrads and 53% of the TGQN grad students indicated that they had experienced sexual harassment, compared with 59% and 37% of the cis female undergrads and grad students, respectively. The TGQN undergrads had a similar rate of experiencing nonconsensual sexual contact by force or inability to consent as their cis female counterparts (23% vs. 26%), whereas the rate was significantly higher for the TGQN grad students (15% vs. 10%). A 2015 AAU study, which included slightly more than 150,000 participants, likewise found that trans students are more likely than their cis peers to experience sexual violence on campuses.

But even with such high rates of abuse, many of the TGQN respondents in both AAU studies thought that reporting incidents of sexual harassment and assault would further victimize them, seemingly because they did not have faith in the system on their campus to support and protect the rights of trans people. The TGQN students were less likely than the cis female and male students to believe that a report of sexual harassment or assault would be taken seriously, that a fair investigation would be undertaken, and that college officials would protect the victimized student's safety and address the factors that may have led to the attack. In addition, the TGQN students were more likely to state that the alleged perpetrator(s) or others would retaliate against the victimized student in response to a report of sexual harassment or assault. Given that many colleges have few if any trans-inclusive policies and are seen by trans students as doing little to address the negative campus climates they experience, it is not surprising that the students would not trust their institution to support them even when they have been sexually victimized.

Improvements Over Time

Among the U.S. Transgender Survey participants who wrote about their time in college, those who described having a positive college experience overall were mostly the younger respondents, especially members of Gen Z (i.e., individuals 18–24 years old at the time of the survey). The Gen Zers were the most likely age group to state that they felt safe and could be out on campus and to indicate that they received support from faculty, staff, administrators, and peers. The generally more positive experiences of trans students in the 2010s seemingly resulted from the efforts of a growing number of colleges to create more inclusive and supportive environments for their trans

community members. But all colleges can do much more to improve their negative campus climates, challenge gender binary structures, and foster trans inclusion.

Campus Residence Halls

Campus residence halls embody the importance of peer interactions and socialization among undergraduate students. A majority of students' time is spent in their residences, and the volume of their interactions and experiences can have profound effects on their overall success in college. Living on campus has numerous benefits, including creating meaningful connections with staff and peers, developing autonomy and self-reliance, and increasing one's sense of belonging. But as important as residence halls are for student success, the benefits are not shared equally and not accessible to all students. Trans students in particular must navigate institutional and interpersonal exclusion, given the cisnormative structure of most residence halls. In response, some colleges and universities are seeking to develop more trans-supportive housing practices.

Institutional and Individual Discrimination

Historically, residence halls have been divided by sex, and many are still sex segregated across an entire hall, by floor, or within suites or rooms. On most campuses in the United States that provide housing, residential housing assignments are based on a student's legal, binary sex designation of female/male. As a result, trans students are often assigned to the wrong gendered room or are denied campus housing completely. In addition, bathrooms in residence halls are typically multiuser facilities that are designated for women only or for men only, further limiting the ability of

many trans students to have a safe, comfortable place to live.

Interpersonally, trans students often have to navigate transphobic and cisnormative interactions with residence hall peers and staff. Because housing is traditionally assigned by binary sex designations, students typically make assumptions about who should be in gendered spaces such as residence hall rooms and bathrooms. As a result, trans students may experience covert microaggressions or overt discrimination, which can negatively affect their physical, mental, and academic well-being.

Gender-Inclusive Housing

To meet the needs of trans students, some schools are implementing gender-inclusive housing (GIH; sometimes referred to as gender-neutral or all-gender housing), in which students of any gender can choose to live together in a campus residence hall. The structure for GIH varies, but most involve roommates of any gender sharing a room on a mixed-gender floor or sharing communal living space and sometimes bedrooms in suite- or apartment-style housing. The extent to which the bathrooms in GIH are gender inclusive also varies and is often dependent on the physical design of the building. In addition, the availability of GIH may be restricted, such as by not being available to first-year students or requiring students to explain their need for it.

On many campuses, accessing GIH requires an additional application process and/or an interview with a staff member. Even if these administrators are well intentioned and trained, they may be unknown to, and therefore not trusted by, students, and such a process requires students to out themselves. Some students, especially those who have had negative institutional experiences because of being trans, may not want to ask for help in navigating campus housing.

A lack of gender-inclusive housing forces some trans students to move off-campus, where they may encounter other negative consequences, such as feeling disconnected from campus activities, resources, and community; food insecurity; housing discrimination; and greater financial instability. Students with multiple marginalized identities likely experience an even greater negative impact.

LGBTQIA+ Housing

Along with or sometimes as a part of gender-inclusive housing, some campuses offer an LGBTQIA+ suite, floor, or house, where LGBTQIA+ students and allies can be in a supportive environment and develop their own specific community. LGBTQIA+ housing differs from GIH in that not all LGBTQIA+ housing allows students to live with others of any gender, and some LGBTQIA+ housing includes specific programming related to LGBTQIA+ experiences. In addition, GIH is typically open to anyone wanting to be housed with someone of a gender different than themselves, so it is more a type of housing accommodation than a community or theme housing, as GIH is thus not limited to trans people (for example, two cis friends or family members may decide to live together).

LGBTQIA+ housing does not always serve the needs of trans students. Not all trans students want to be out about their gender identity, and not all identify as queer and want to live in a queer community. At the same time, some cis LGBQIA+ students are transphobic, so LGBTQIA+ housing is not necessarily a safe space for trans students. In addition, LGBTQIA+ housing is often a partnership between Residential Life and an LGBTQIA+ Center, and both offices are not always adept at meeting the needs of trans students.

Research on Residence Halls

Most of the research on trans students' experiences in residence halls focuses on the housing itself and bathrooms. Other issues are rarely explored, such as interactions with resident assistants and with professional staff, many of whom are new graduate students. In addition, there is no campus housing research that examines possible differences among students with different trans identities or the specific experiences of trans students with multiple marginalized identities, such as trans students of color, first-generation trans students, and trans students with disabilities.

Implications

Campus housing policies and practices, as well as research in this area, need to consider the comfort, safety, and privacy of trans students in existing

residence halls and in the construction and renovation of facilities. Policies and practices that uphold the gender binary make trans students more vulnerable to negative mental health outcomes, academic challenges, and a lower sense of well-being. In order for residence halls to be trans inclusive, it is recommended that housing officials stop using sex assigned at birth as the criterion by which they make housing assignments and recognize the specific needs of trans students, which includes involving them in trans-related policy decisions.

Cancer

A dearth of research exists exploring trans individuals' experiences of cancer diagnosis, treatment, and survivorship. As gender identity (GI) data are not included in many national data sets, such as the Surveillance, Epidemiology, and End Results (SEER) Program of the National Cancer Institute or cooperative groups, data regarding cancer prevalence, risks, and outcomes for trans people are significantly hampered. Limited, retrospective data among small cohorts suggest that trans people have higher rates of specific types of malignancies, including those associated with human immunodeficiency virus (HIV) and human papillomavirus (HPV), but no increased risk of other cancers overall. However, larger scale data are urgently needed so that any disparities in resources and cancer care accessibility that may affect cancer risks, treatment, and outcomes may be identified and intervened upon as these may significantly affect the health and well-being of trans people and communities.

Risk of certain cancers may be increased in trans people due to the following:

- minority stress on trans persons may increase their cancer risks;
- lack of access to competent care, coupled with discrimination within health care, limits screening and prevention efforts;
- rates of tobacco use may be higher in trans populations;
- rates of alcohol consumption may also be higher; and
- higher rates of HPV and HIV may result in higher rates of certain cancers in trans people.

Gendered Assumptions in Health Care

As is the case for all people, you cannot know what anatomy trans people have or what hormones are in their bodies unless you ask them. This is made more difficult by lack of standardized means to properly record details about trans people in electronic health records. For example, the gender marker in the chart may indicate sex assigned at birth or gender identity. As such, it is critical that clinicians and other health professionals accurately collect and document patients' sex assigned at birth, gender identity, and anatomy.

Trans people may experience a number of barriers to care that may delay cancer diagnosis. Trans patients may have negative experiences such as verbal harassment and refusals of treatment within medical settings that result in barriers to care. For a number of trans people, cost is also a major barrier. Trans people may also present to oncology care late because they have not been

screened appropriately based on their anatomy. For example, providers may avoid conversations about prostate cancer screening with transfeminine people in their 50s and 60s, although this is the recommendation by the U.S. Preventive Services Task Force for cisgender (cis) men. Furthermore, it is critical for providers to be familiar with how anatomy could be altered by gender-affirming surgical care (e.g., vaginoplasty for transfeminine people does not remove the prostate). Thus, providers should ask, in a sensitive way, about anatomy, if relevant, and make preventive care and screening recommendations accordingly. For more information about screening guidelines, visit the UCSF Transgender Care and Treatment Guidelines.

Gendered Aspects of Cancer

Gendered expectations may pressure patients to conform in ways that do not match their values or identity. For example, breast cancer treatment has been thoroughly "pink washed." Patients with breast cancer may be expected to undergo breast reconstruction, attend makeup classes, or wear long-haired wigs. Patients with prostate cancer may be expected to respond to narratives about "being a fighter." Forms may include a section "for women only" with questions about menstruation or childbearing. Questions that assume anatomy based on gender may not be relevant to trans people and may force patients to choose between lying and coming out. This gendering of the cancer care continuum can exclude or render invisible the experiences of trans people or other people such as cis men with breast cancer. For trans people, in particular, this may lead to an overall feeling that one's gender is being misread or misunderstood by providers and the medical system. Thus, the potential exists for trans patients to experience significant distress when receiving cancer care. Providers and health care systems can help by renaming clinics and other health care spaces so that they are gender neutral, using gender-neutral language, avoiding gendered expectations, asking for and using correct pronouns and names for patients, and eliciting and using words patients prefer regarding their anatomy. These changes could make health care inclusive to people of all genders, particularly people who are nonbinary.

Ways to improve cancer care to be more inclusive of trans people include the following:

- Make gender-neutral bathrooms accessible.
- Take gender markers off identification bracelets.
- Ask for and use the correct pronoun and name for patients.
- Ensure that forms include options that are relevant to transgender and gender-diverse patients.
- Be informed.
- Share medical decisions with patients.

Because cancer therapy can often involve surgery, surgeons should ask whether trans patients, and all other patients, desire a particular form of surgery. Trans people may be interested in breast augmentation, mastectomy, or mastectomy with nipple reconstruction or tattoo, as may other patients. Trans people with prostate cancer may be interested in orchiectomy (removal of the testes) as part of their treatment. These surgeries could dovetail with transition-related care. Trans people may also be concerned about how surgery may affect their prior gender-affirming procedures. For trans individuals who may not have had the resources or opportunity to undergo gender-affirming procedures, surgical care in the context of cancer treatment can have a significant overlap in achieving a more gender-affirmed self. And although some data indicate that the risk of breast cancer may be increased for people on estrogen therapy, discontinuation of hormones can result in significant gender dysphoria and distress, including suicidality. Addressing the continued use of hormone therapy should prioritize patients' wishes in the context of a discussion of risks and benefits.

Follow-Up

Given the uncertainty of how hormone therapy affects occurrence of hormone-sensitive cancers, more frequent follow-up may be required until more definitive research is available to provide evidence-based care. Additionally, cancer care providers would benefit from reviewing the current literature regarding risks and benefits of hormone therapy so that they may provide balanced information to their trans patients, including

regarding how cancer treatment might affect gender-affirming care, particularly future options for gender-affirming surgery.

Not surprisingly, trans cancer survivors report lower satisfaction with care than do cis cancer survivors, even controlling for demographic and clinical variables associated with care. Furthermore, the lack of sexual and gender minority–specific survivorship support groups and networks for both cancer survivors and loved ones is a missed opportunity to provide complete and compassionate care. Nonbinary people may encounter particular roadblocks, including providers expecting them to fit male or female gender expectations and providers not using gender-neutral pronouns.

Cancer Survivorship

Cancer survivorship describes the experience of living with, through, and beyond cancer. It is unknown how many cancer survivors are trans or gender diverse, because cancer registries do not collect such data. LGBTQIA+ populations are described as an "invisible diversity" in cancer care. Cancer research and clinical practice are predominantly heterocentric and ciscentric, resulting in insufficient knowledge about the specific health care needs, outcomes, lived experiences, and effective interventions to improve outcomes for LGBTQIA+ populations. There is an emerging field of LGBTQ cancer survivorship research. However, this has focused on cisgender LGBQ women and men. Previous research on trans people and cancer has focused on epidemiology, etiology, and biomedical aspects of cancer treatment. There is a pressing need for research to examine the cancer survivorship experiences of the trans population, in order to inform practice and policy, as well as the development of culturally competent cancer information and care.

There are a number of areas where trans cancer survivors may have unique experiences or concerns. Cancer and cancer treatment can have an impact on gendered embodiment—a person's sense of self as a gendered being, located in the body. For trans people, embodied changes resulting from cancer may increase or decrease gender dysphoria. A bilateral mastectomy is medically similar to gender-affirming "top surgery," which may facilitate an alignment between masculine or nonbinary gender identity and embodiment. Some LGBTQIA+ individuals embrace the choice to forgo breast reconstruction after mastectomy, deciding to "go flat" (also known as "flattopping"). Conversely,

mastectomy may be perceived to erase self-perceived femininity or reverse embodied changes that have occurred as part of gender affirmation, and breast reconstruction may be welcomed.

Some cancers are treated using hormone therapies, while others are hormone sensitive, in both cases interacting with hormones used as part of gender affirmation. Cancer treatment decisions may thus have significant and enduring impacts on trans survivors' gender identity and expression. Other bodily changes, such as treatment-related hair loss, weight gain or weight loss, incontinence, and changes to sexual functioning, may affect embodied experiences of gender or sexuality. Changes in erectile functioning after cancer treatment are known to have a negative impact on the psychological well-being and identity of gay and bisexual men. This may also be the case for trans people with a penis; research is needed to investigate this issue. Cancer-related embodied changes may be complicated by gender-affirming procedures. Urinary incontinence following vaginoplasty can be exacerbated by cancer treatment and may also affect bowel incontinence. Dilation of the neovaginal canal to prevent stenosis (narrowing and shortening of the vagina) may also be affected by vaginal dryness or surgery.

Access to culturally competent cancer information and care has a significant influence on survivorship outcomes. Experience or fear of discrimination in general health care may continue into cancer care, contributing to trans people's feeling of distrust and anxiety when accessing cancer services. This can result in avoidance of cancer screening and delays in medical help seeking. Disclosure of one's trans identity can be associated with feelings of discomfort, embarrassment, and fear of treatment refusal, as well as privacy concerns. Trans patients are often invisible on intake forms and only disclose their trans status when asked. Hostility on the part of cancer care professionals toward LGBTQIA+ people is commonly reported, including misgendering or use of inappropriate language to describe trans people. Trans people report feeling unwelcome in oncology clinics and cancer support groups, sometimes being asked to leave due to gender nonconformity. Heterocentric assumptions held by health care providers can lead to same-gender partners being marginalized or excluded. The binary gendering of some cancers, such as breast cancer being seen as a "women's cancer," perpetuates the exclusion of trans people. In combination, this can lead to cancer care and information that is poorly tailored or inappropriate for trans people and their partners, as well as to trans people having limited access to cancer peer social support. This can contribute to distress in what is already a challenging time.

Many trans people experience health inequalities, which can adversely affect mental and physical health during cancer survivorship. Higher rates of poverty and lower rates of health insurance can affect ability to access health care, in the absence of universal free health care. The impact of trans discrimination in cancer care can exacerbate minority stress arising from familial rejection, social exclusion, discrimination in the workplace, and physical or sexual violence. This may be more acute for those who occupy multiple marginalized positions, such as racial and ethnic minorities, those who are sexuality diverse or have intersex variations, those who have disabilities, and those who are exploring or questioning their trans identities, including adolescents and young adults.

Many health professionals receive no training on the care of trans people, contributing to deficits in knowledge of the cancer-related needs of trans patients and their partners. There is a need for education and training to improve awareness of the intersection of cancer and gender-affirming health care, as well as a need for trans-specific resources and information to facilitate positive outcomes in cancer survivorship.

Career Development and Trajectories

Career development is an overarching concept that describes the evolution of work and personal activities and commitments over time. It is a lifelong process with particular implications for trans individuals. *Career trajectories* are one element of overall career development, typically describing the sequence of an individual's education and work. Career development and trajectories are not limited to discussion of paid employment but rather the *processes* and *pathways* through which individuals explore and make decisions about their futures.

Career development and trajectories are specific to individuals, and there are professional fields whose goals include assisting individuals with career planning and decision making. Career or vocational psychologists focus on individual factors such as education, personality, opportunity, and agency in the processes of career development. Gender identity and systems of oppression based on gender—especially sexism, genderism, and transphobia—interact with career development to both afford and constrain aspirations, opportunities, agency, and trajectories of trans people.

Career Exploration and Job Search

There are several decisions that trans individuals make in relation to work and career that influence their trajectory, work satisfaction, and well-being. Before starting work, trans people may experience what researchers call a bottleneck in their overall development as psychological resources are taken up with gender identity exploration and coping with discrimination and harassment. This bottleneck draws personal resources away from vocational and career exploration, potentially creating a disadvantage for trans youth as they prepare to enter their working lives. Trans youth and adults who go to college may also experience a lack of support for career exploration and development from career services offices that are not well prepared to serve them. Similarly, high school guidance counselors and adult vocational counselors may lack knowledge and sensitivity to provide high-quality support for the specifics of trans people's lives. It is important to remember that factors other than gender have a substantial influence on career exploration and opportunity; on their own and in intersection with gender, factors such as race, age, socioeconomic status, and ability are also influential.

Workplaces reflect the gendered nature and assumptions of the wider society, sorting many jobs into a masculine–feminine binary. For example, teaching and nursing are typically considered "female" occupations in the United States, whereas construction and military are classed "male." Not all occupations are gendered to the same extent; clerical/administrative assistant and firefighting are more strongly associated with feminine and masculine, respectively, but fields like physical therapy and accounting are less so. Increasingly, life science and medicine are seen as inclusive of women, although having women join "male" fields has done little to change perceptions that the world of work is divided into binary categories. The assumption that there are only two gender options also excludes people whose identity is nonbinary or gender fluid.

Thinking about jobs in gendered ways can influence career aspirations and pathways. Trans youth may align their goals with these binary conceptions of feminine or masculine careers and face some resistance, or at least curiosity, from peers and adults who see the goals as incompatible with the young person's perceived gender. Conversely, awareness that gender is not binary may enable trans youth to see beyond the artificial categorization of jobs into feminine and masculine, opening opportunities for exploring careers without framing work in gendered terms. Nonbinary and gender-fluid youth may approach career selection and planning without the constraints of complying with gendered expectations.

Trans people may perceive some careers or workplaces as more open to them, potentially shaping career aspirations and job seeking. Working in a field that is less strongly gendered may attract trans people who do not want their jobs to reflect the masculine–feminine binary. The perception that gender does not matter as much for success in these fields could make them seem more open to gender diversity. Conversely, working in a strongly gendered field might appeal to some trans individuals who want their careers to reinforce their expression of their gender; for example, a trans man might choose a "male" field that aligns with his gender identity and expression, and a trans woman might elect a "female" field that aligns with hers. Some fields that are not strongly gendered in the masculine–feminine binary may still strongly enforce cisgenderism, however, making it difficult for nonbinary people to see themselves in these jobs; in essence, the message is "It's OK to be either a man or a woman in this field, but you have to be one or the other."

The job search process presents particular opportunities and challenges for trans people. Searching for and starting a new job represents a chance for a fresh start in which one can represent one's gender perhaps differently from how one did in school or previous jobs, reducing or eliminating the need to out oneself as trans. Trans job searchers must contend with a set of legal and policy considerations: Does the employer or its locale provide protection from discrimination and harassment based on gender identity? What options exist for redress if there are violations? If the employer provides health benefits, do they cover gender-affirming services? Career and vocational counselors should be aware of these issues and help trans job seekers learn how to find the answers.

If a trans person's name and/or pronouns have changed over time, they may feel the need to out themselves to prospective employers in the application process or to omit previous employment from their work history. Similarly, to avoid being outed, someone who has transitioned may not want to use job references from previous employers. School and university transcripts, professional licenses, recognition and awards, and resumes may carry different names over time. Changing a first name at some point in the career may seem confusing to potential employers or present obstacles to representing a continuous work trajectory.

Workplace Gender Climate and Its Influence on Careers of Trans People

Regardless of whether a field as a whole is highly gendered or less so, individual workplaces have their own climates for gender diversity. Gender climates have a direct influence on the people who work within them. Gender climate may be influenced by a number of factors, including the employer's policies and practices related to nondiscrimination, gender diversity education and training for employees, provision of gender-inclusive health care and other benefits, local climate for gender diversity, and local, state, and national employment laws. Day-to-day experiences in the workplace affect the performance, well-being, and job satisfaction of trans employees, as well as their long-term prospects for developing a successful career. Workplace climate is the responsibility of the employer, although the effects are seen on individual employees.

Policies and practices related to gender inclusion may strongly influence career trajectories of trans people. The opportunity to be hired, to work, and to be rewarded for job performance without discrimination and harassment is critical to career success. Trans people may be deterred from entering or advancing in preferred careers by repeated experiences with discrimination or harassment. Some trans people develop and enact second- and third-choice career plans as ways to deal with inequitable treatment in the workplace. Some find an equitable, supportive workplace at some point in

their career and stay in those positions rather than pursue others that might advance their careers.

How other people perceive and treat coworkers is one aspect of workplace climate. Regardless of gender identity, every employee makes decisions about dress, physical appearance (e.g., hairstyle, facial grooming), and communication (e.g., voice, inflection, vocabulary). Some careers and workplaces convey strong expectations, even requirements, for employees' gender presentation. Some dress codes or uniforms are based on binary gender assumptions (e.g., skirts for women and pants for men) that do not offer options for nonbinary individuals (e.g., wearing a shirt and necktie with heels).

For trans people, decisions related to gender presentation may carry weight in career choices because they signal alignment or misalignment with identity. Working in a field that supports gender diversity reduces the emotional and cognitive load of constant self-monitoring of one's gender presentation, which may have particular benefits for nonbinary people. Trans people with the option to do so may select jobs in fields that provide opportunities to align their gender presentation with their identities or provide flexibility to express gender differently at different times in a single workplace or across the career.

Workplaces and fields that offer positive and inclusive gender climate may be particularly attractive to trans people, allowing them to build successful, satisfying careers. Not all trans people have the socioeconomic, educational, racial, and/or citizenship privileges necessary to freely choose jobs in gender-inclusive workplaces. Workplace climate is one manifestation of the effects of intersecting systems of oppression that dampen trans people's access to the full array of potential jobs and to career progression.

Transitioning at Work and Career Development

Although not all trans people undergo gender transition, transitioning at work may have specific effects on career trajectories of trans people. In addition to the general influence of gender climate and matters of nondiscrimination, transitioning at work brings particular opportunities and challenges for careers. Posttransition can be a time of possibility and growth in career. Freed from some of the psychological stresses of pretransition and transition, a posttransition person may be able to more fully explore career interests and plan for job change or career advancement. Transition may facilitate acceptance within a gendered field; for example, a female-to-male computer scientist may find himself more accepted in a predominantly male work setting. For trans people who work in inclusive contexts, the affirmation of coworkers may reinforce a positive decision to transition, contribute to job satisfaction, and promote a sense of well-being in career settings.

Transitioning at work can also pose challenges to work and career trajectory. The transition process may result in heightened visibility and negative repercussions from coworkers and superiors. Transphobia that was not previously evident may surface when someone changes appearance, name, or pronouns. In highly gendered fields, transitioning may mean being seen as less knowledgeable, as when a male-to-female trans person encounters workplace sexism in a field that is predominantly male. Trans people report losing relationships and standing in professional communities due to transphobia. As previously noted, transitioning at work can interrupt careers that are built on continuity of name and reputation. Navigating these potential obstacles can draw energy away from contributing to work and career. For these reasons, transition at work can decrease career prospects.

Trans people may choose to stay in a job or seek a new job before or after transition. Access to health insurance is one factor, as is the financial stability of keeping a job throughout what can be a costly process that often is not covered by insurance. Staying with a supportive employer is another reason to keep a job, while finding a new workplace, if possible, may be important posttransition if the climate is or becomes unsupportive.

Career counselors in any setting can work with trans clients to anticipate and mediate some of the negative consequences while building on the possibilities presented by transition at work. Training for career counselors can include awareness of trans identities, the transition process, and the possible effects of transition on work. Accounting for career and work identity among the many considerations for transition can help prepare trans people in advance. To support trans career development,

human resources and other employer units can take responsibility for creating an inclusive, affirming workplace climate for trans people overall and proactively in advance if they become aware that someone will transition at work.

Chest Feeding

This entry discusses lactation and infant feeding for transgender and gender nonbinary (trans) people. The term *chest feeding* refers to a person's ability to produce and express milk from mammary and ductal tissue in the chest to feed an infant. This term is preferred when discussing this practice among trans people, because it is gender neutral and more acceptable to people on the transmasculine spectrum who may be reluctant to use gendered language to refer to their body. It also accurately describes the practice in transfeminine people. The following sections address chest feeding for both transmasculine and transfeminine people, including special considerations with hormonal treatment.

Transmasculine Chest Feeding

The term *transmasculine* refers to those who were assigned female at birth and whose gender identity is on the masculine spectrum. Many trans people who are female assigned at birth may identify as nonbinary, meaning they do not identify as male or female. However, chest feeding is dependent on physiology rather than identity, and both transmasculine and nonbinary people with the necessary tissues are able to chest feed. Transmasculine and nonbinary individuals retain the ability to become pregnant and chest feed their infants as long as their uterus, mammary, and ductal tissues are intact. In a single study published in 2014 by Alexis Light et al., titled "Transgender Men Who Experienced Pregnancy After Female-to-Male Gender Transitioning," 51% of transmasculine participants chose to chest feed after delivering their child or children.

It may be possible to complete chest masculinization without compromising the ability to chest feed, but this may compromise aesthetic outcomes because mammary and ductal tissue will have to be left in the chest and remain attached to the nipple. In 2018, Christine Jaslar published the only available case study to date of one person's experience attempting to express milk after double-incision chest masculinization with free nipple grafts. He was able to express 15 mL of milk from one nipple and only droplets from the other while off testosterone treatment. While it is unexpected that he would have any milk production after a free nipple graft (a process during chest masculinization in which the nipple is completely removed from the body, thinned, and reattached), he was unable to produce enough milk to adequately feed an infant.

Staying on hormone therapy while chest feeding is a common desire for transmasculine people with

children. While the National Institutes of Health reports that testosterone is not significantly expressed in chest milk, it has only been studied in doses many times lower than those used in masculinizing hormone therapy for transgender people. Testosterone has also been used historically to suppress lactation, usually in combination with estrogen, and may interfere with milk production in mammary tissues.

Pregnancy alone after chest masculinization surgery is also associated with visible changes in the chest. These changes occur because chest masculinization is an aesthetic procedure meant to create a masculine-appearing chest and often involves leaving some mammary and ductal tissue behind to help create a masculinized contour to the chest. Hormonal changes during and after pregnancy cause those tissues to swell. In 2016, Trevor MacDonald asked several transmasculine parents about their experiences with pregnancy. Participants with less-invasive chest masculinization procedures (i.e., liposuction instead of double-incision techniques) reported greater swelling in their chest than did those with more invasive techniques. However, there were too few participants to suggest these differences would be universal.

It is worth noting that all studies referenced in this section involving transmasculine people found their participants via online convenience samples. All participants recruited in this way were white and identified as on the transmasculine spectrum. Trans people's experiences are diverse and highly varied, and these data do not represent the entire population of transgender people wishing to chest feed.

Transfeminine Chest Feeding

Transfeminine people, or those who are male assigned at birth and whose gender identity is on the feminine spectrum, can chest feed but require hormonal treatment in order to do so. Nonbinary people who are male assigned at birth also require hormonal treatment in order to chest feed, and it is important for clinicians to discuss with patients that mammary and ductal tissue development is the goal of this treatment, since nonbinary people may prefer to avoid developing a female-appearing chest.

A single case report published in 2018 by Tamar Reisman and Zil Goldstein describes a transgender woman who was able to chest feed an infant birthed by her cisgender female partner for 4 months without supplemental nutrition. She was treated with estradiol, progesterone, and domperidone paired with aggressive nipple stimulation. Estradiol and progesterone were used to mimic the hormonal state of a pregnant cisgender woman, and the patient ordered domperidone from Canada to initiate self-treatment because the substance is not approved for this use in the United States. It is also important to note that high estradiol levels can suppress lactation in postpartum cisgender women, so the patient was treated with a low-dose estradiol patch after delivery of her baby.

Although this treatment was effective for this patient, it is unclear what elements of therapy are necessary to effectively allow a transgender woman to chest feed. As noted earlier, it is necessary for mammary and ductal tissues to be present, which are best developed with the use of feminizing hormone therapy protocols. However, there have been no trials testing different medication and nipple stimulation regimens and their efficacy in supporting infant nutrition. The nutritional content of the milk transfeminine people produce has also not been evaluated. Taking estrogen while lactating may also inhibit milk production; however, the U.S. National Institutes of Health suggests that the use of transdermal estradiol patches does not result in significant estradiol concentrations in breast milk or infant blood samples.

No studies of lactation after breast augmentation have included transfeminine people. Some small studies among cisgender women report differences in lactation depending on the location of the incision and placement of the implant. Larger studies, however, have not validated these findings. One study in 2018 conducted by Lisa Bompy and her team followed cisgender women 5 years after implant placement and found no significant differences with incision location and implant placement; however, people who had undergone mastopexy (sometimes called the "internal bra" procedure whereby muscles are moved to help hold up the implants) were more likely to have inadequate milk production when attempting to chest feed.

Conclusion

Although understudied, trans people are capable of chest feeding infants regardless of birth anatomy. Chest feeding requires hormonal intervention for those who are male assigned at birth, and chest masculinization interferes with chest feeding for those who are female assigned at birth. However, chest feeding is possible for those who have an intact connection between the nipple and the mammary and ductal tissues in their chest.

Child Welfare System

Trans youth are an often-ignored group in child welfare research and services. Yet, research has shown these youth are overrepresented and experience disparities in the child welfare system, warranting a specific focus on their needs, experiences, and outcomes. Facilitating and supporting transitions from out-of-home care (also known as foster care) to permanent safe and loving homes is the ultimate goal of child welfare agencies. Several factors affecting permanent placements into homes (i.e., "permanency") have been studied. A high proportion of youth in out-of-home care face various risks to achieving permanency, including mental health issues, trauma, homelessness, and involvement with state-level institutions such as the juvenile justice system. Many studies find sex/gender are not strong predictors in achieving permanency, although they also find that sex/gender affect day-to-day foster care experiences. Most research, however, is narrowly focused on sex and gender as synonymous constructs and do not attend to gender diversity beyond the cisgender female–male dichotomy. Trans and other gender minority youth (e.g., nonbinary, gender-nonconforming cis youth) are a group that warrant more attention in this field.

Gender Diversity of Youth in Foster Care

When trying to understand the characteristics and experiences of the trans and other gender minority youth population in foster care, only one representative study has measured gender identity in this population: the Los Angeles Foster Youth study (LAFYS). Research from that project shows that how youth experience foster care and risks to

permanency differ according to how gender is understood and defined. In their work, LAFYS researchers intentionally highlight the overlap of sex assigned at birth, gender expression, and gender identity. For example, compared to cis heterosexual youth, trans youth were two times more likely to be gender nonconforming (GNC), and a higher proportion of youth assigned female at birth were GNC or identified as LGBTQ compared to males. Youth defined as GNC were also more likely to identify as LGBTQ or female than youth defined as gender conforming. Researchers also found that youth who identified as sexual and gender minorities were more likely to present as GNC. Further, the differences between LGBTQ and non-LGBTQ youth experiences differed by sex assigned at birth. Female LGBTQ youth were more likely to experience some challenges compared to male LGBTQ youth, such as experiences with arrest or worse treatment in foster care systems. On the other hand, male LGBTQ youth were more likely than non-LGBTQ male youth to experience homelessness. Thus, sex assigned at birth, gender identity, gender expression, and sexual orientation represent distinct, yet highly interconnected, identities.

Overrepresentation of Trans Youth in Foster Care

Trans youth are overrepresented in the foster care system. Among the full LAFYS sample of youth in out-of-home care, 5.4% were categorized as transgender, meaning either they used the term *transgender* to identify themselves or their sex assigned at birth was different from their current gender identity (e.g., assigned female at birth and now identifies as male or as a boy). Given that estimates of trans youth in the general population range from 0.7% to 1.8%, this proportion of trans youth in foster care suggests they are overrepresented. Further, 11% of all youth, regardless of gender identity and sexual orientation, were highly gender nonconforming—meaning, they scored high on a measure of gender expression that in the dominant culture is seen as discordant with their birth sex (e.g., a youth assigned male at birth reports being seen as highly feminine). It is also notable that across all groups, trans youth, and youth who are not trans, youth of color represent a disproportionate majority of those in foster care. These data indicate a significant proportion of the foster care population that have unique needs and concerns in the context of the system's level of preparedness for finding them permanent homes.

Trans Youth Disparities in Foster Care

For decades, qualitative studies and clinical accounts that address trans youth in social services have shown that they tend to have negative experiences connected to people's responses to their gender identity. Rejection, abuse, and discrimination affect LGBTQ youth more broadly while they are in out-of-home care. At various points in time while in the child welfare system, these youth interact with case workers, foster parents, congregate care facility employees, and other foster youth. Prejudice has reportedly manifested in disturbingly common practices such as deeming these youth "unadoptable," blaming their being "out" for the harassment and abuse from others, housing them in isolation "for their own safety" or to avoid their "preying on other youth," repeated placement moves resulting from the discomfort of a caregiver, or disciplining LGBTQ youth for engaging in age-appropriate conduct that would not be punishable were it between youth of different "sexes." Research documenting rates of maltreatment of trans youth in foster care are rare, as mentioned above, because gender identity (in a way that is inclusive of trans identities) is often not measured in studies. However, the LAYFS research found that transgender youth experienced expulsion or suspension from school more times in the past year than their cisgender heterosexual peers. Also, they reported similar patterns to LGBQ youth who tended to be placed in groups homes more often, were hospitalized for emotional reasons, and reported not being treated very well by the child welfare system compared with heterosexual cisgender youth.

Conclusion

The growing interest in LGBTQ youth in foster care is promising, although there is much more work to be done. Currently, child welfare agencies are not collecting data that identify who their

sexual and gender minority youth are, making it difficult to understand whether conditions are improving or worsening for them across the country. Research to date indicates the usefulness of looking at distinct but related aspects of one's whole identity together—namely, gender identity, sex assigned at birth, gender expression, and sexual identity. Increasing the collection of data that measure all of these aspects is an important next step in understanding and improving the experiences of trans youth in the child welfare system.

Children With Trans Parents, Psychosocial Outcomes

On the basis of existing data, it is estimated that between 25% and 50% of trans adults have at least one child. In general, trans parents are likely to have transitioned later in life, after having children, but options are becoming increasingly available for trans people to become parents after transition. Although most studies with trans parents focus on the parent's experiences and their well-being specifically, few have addressed the experience of being a child with a trans parent. This entry discusses known psychosocial outcomes for children of trans parents, including how they may adjust to having a trans parent or dealing with stigma related to being in a family with a trans parent. It also addresses the unique challenges that trans parents face and factors that promote well-being in children of trans parents.

Unique Challenges Faced by Trans Parents

Trans people are more likely than their cis peers to experience oppression, discrimination, and various other stressors because of their trans identity. This minority stress, or stress specifically related to their trans identity, can lead to disparities in mental health concerns, substance use, or medical issues. Trans people also frequently experience social stigma and lack of acceptance related to their gender identity. Along with these stressors, trans parents may face unique challenges that can directly and indirectly affect their children. All parents face general stressors related to parenthood, but there are unique experiences for trans parents. For example, trans parents may experience discrimination or face social stigma within their child's school system due to lack of acceptance of trans identities. Additionally, trans people often have difficulty finding adequate health insurance or housing, both of which can directly affect their children. Trans people are also affected by the prevailing stereotype that children's well-being will be negatively affected by having a trans parent. Despite studies that show the contrary, many people who interact directly with trans parents and their children

still hold this belief, which exacerbates the stress experienced by trans parents and their children.

Parents Who Transition Prior to Having Children

For those who have come out or transitioned before having children, it can be challenging to decide when and how to disclose their trans identity to their children. Most of these parents are open about their trans identity from the time that their child is born or tell them at a young age. Children who know from an early age generally experience less distress about having a trans parent than those who find out when they are older. Some parents choose to wait to share information about their gender identity until their child is older, and reasons for waiting vary. Among those who wait, parents may believe that older children will understand the information better than younger children. In these situations, children can experience confusion or even feelings of distrust toward the parent. They may have a challenging time understanding why they were not told sooner or feel ambivalent about their parent's identity. Conversely, some children have a more neutral or positive reaction to learning about their parent's identity and approach the situation with curiosity and a desire to know. In some cases, parents choose to wait because they fear that their trans identity could affect the child's safety or lead to overt discrimination. This is generally more of a concern among parents who live in areas that are more oppressive and stigmatizing against trans people.

Parents Who Come Out as Trans After Having Children

Among parents who come out as trans after having children, the most common challenge is generally coming out to their children and family. This coming-out process directly affects their children and is usually not a neutral event, regardless of the children's ages when this occurs. A parent coming out is a unique experience that often leads to an array of emotional experiences, including grief, feelings of loss, anger, or confusion. There is often fear or concern about how the children will react to the parent's transition. Not all trans individuals go through a physical or medical transition, but many will socially transition (e.g., use different pronouns, use a new name, or dress in a way that feels more congruent with their identity). Such transitions can present a unique challenge because children may have a difficult time accepting these changes. Many children face an adjustment period during which they learn to use different pronouns or become used to seeing their parent dress differently. This experience is also unique, as many parents may have to discuss what title their children will use. For example, some trans mothers may still be called "dad" by their children, whereas some families may decide to use "parent" instead of "mother" or "father." Additionally, many trans parents are influenced by traditional genders roles, which can affect their parenting style. Fathers are generally seen as more of the disciplinary parent, for example, so trans men may feel the need to shift their roles to meet this expectation. Generally, trans parents and families who have a more open-minded or less restricted view of traditional general roles show better adjustment.

In a 2019 study by Jaclyn Tabor, titled "Mom, Dad, or Somewhere In Between: Role-Relational Ambiguity and Children of Transgender Parents," the author presented general themes on how children deal with a parent coming out and the ambiguity of their parents' roles. In dealing with this role ambiguity, the author found that children of trans parents generally deal with the transition in one of three ways. Some children choose to become emotionally or physically disconnected from their trans parent, although this was the least common outcome. Others attempt to resolve this ambiguity by redefining roles or expectations of their parent over time. Examples of this way of dealing with the ambiguity include understanding that a trans mother may still take on a more "traditional dad role" or having views like "that's still my dad, she just happens to be a woman." The final, and most common, way of dealing with this ambiguity is acknowledging the uncertainty and change within the trans parent–child relationship while also attempting to strengthen the relationship. Some children feel as if they are losing a parent after a transition and may try to focus on creating a new bond with their trans parent. Sometimes, this means moving toward a friendship or acquaintance-like relationship with that parent while they work on rebuilding the relationship. Overall, most

children of trans parents actively work toward restructuring and redefining these relationships with the hope of having a meaningful and positive parent–child relationship.

Although the extant research indicates that most families adjust well to a parent coming out as trans, occasionally these experiences can lead to divorce or separation. Fear that this could occur or that it could negatively affect the family in other ways may constitute one reason why a parent waits to, or chooses not to, come out as trans. Separation can occur for a variety of reasons, but chiefly when the trans person's partner is unsupportive or unwilling to stay in the relationship posttransition. Not only can the separation process be difficult for a child, but it is also possible for children to be directly affected by the lack of laws protecting trans parents. Although many states recognize that having a trans identity does not negatively affect a child, some trans parents face considerable bias in divorce proceedings and child custody cases. In some extreme cases, coming out as trans can be a legal basis for granting a divorce or annulment or even terminating their parental rights. Trans parents may lose custody of their children solely because of the belief that their being trans could be harmful toward the child. In evaluating children's adjustment, it can be difficult to determine whether any adverse psychological outcomes that they display are due to the parents' transition or to the overall impact of a divorce.

Psychosocial Outcomes for Children of Trans Parents

There has long been a societal myth that having an LGBTQIA+ parent, specifically a trans parent, could lead to adverse psychological experiences for children. One reason for this myth is fear that children of LGBTQIA+ people are more likely to be LGBTQIA+ identified themselves—a fear that is contradicted by empirical research. Some people also believe that having a trans parent can lead to poorer well-being, including mental health issues, and adjustment difficulties, such as acting out. Contrary to this stereotype, the existing research on children of trans parents shows that their functioning is largely similar to that of children of cis parents. Among children who do experience poor mental health or adjustment difficulties, it is generally due to factors other than their parent's trans identity itself—such as bullying associated with having a trans parent, familial discord, or general developmental challenges.

Indeed, the most common stressful experience reported by children of trans parents is fear of bullying or discrimination owing to their parents' identity. For example, research on trans parents highlights how, according to parents, children may be left out of social gatherings and not allowed to spend time with other children with disapproving parents. For some children with trans parents, these experiences of rejection and exclusion can provoke feelings of depression and anxiety. Although these experiences can be extremely challenging for children, not all children experience them in the same way. Some children of trans parents have also reported that the experience of having a trans parent helped them to become more open-minded, deal with prejudice and oppression, and learn how to enjoy positive aspects of life rather than focusing on the negative. In short, facing adversity because of having a trans parent often promotes the child's ability to cultivate resilience later in life.

Negative or challenging familial relationships can also negatively affect a child with a trans parent. Among parents who separate or divorce after a partner comes out as trans, the child generally faces more challenges. Again, it is often hard to determine if these negative psychosocial outcomes are related to the separation or the parent's identity, specifically. If the cis parent has transphobic attitudes, for example, this may lead to poorer outcomes for the child. Conversely, if the cis parent is accepting of the trans parent's identity and it is clear the separation was not due to their transition, the child may still have a difficult time adjusting to the divorce but may find it easier to cope with their trans parents' transition.

Factors That Promote Well-Being in Children of Trans Parents

Similar to the experience of trans adults, children of trans parents are more likely to face social stigma and discrimination than children whose parents are not in the LGBTQIA+ community. Many protective factors can help children cope with adversity related to having a trans parent or

having a parent come out as trans. Living with and being around people who are accepting and supportive of trans people is one of these most important factors in promoting well-being and resilience in children of trans parents. Having a cis partner or coparent who is unaccepting or stigmatizing often leads to more difficulties for the child. Having a supportive and accepting extended family and friends also enhances a child's ability to overcome adversity related to having a trans parent. In addition to acceptance, the family's sense of coherence and ability to adequately handle conflict is an important protective factor. As is true with all parent–child dynamics, more conflict between parents generally leads to more distress for the child. If the parents can model healthy interpersonal dynamics, the child is likely to benefit. This is especially true during the coming-out process and transition period if a parent comes out as trans after having children.

During the coming-out process, children generally find it beneficial when parents are accepting and understanding of the child's reaction, especially if the child is ambivalent or upset by the information. This allows for a supportive and open conversation between the parents and the child. Having a positive relationship with the trans parent before and during the transition is generally associated with better adjustment for children. Children whose parents undergo physical gender transition may struggle emotionally. Clear communication between the trans parent and the child before and during this process can help to alleviate distress. Among children whose parents transitioned prior to having children, parents tend to be more involved with the LGBTQIA+ community. Such involvement can positively affect the child because they grow up around other LGBTQIA+ people, who are generally more accepting of trans identities.

Having access to support groups and involvement in therapy or counseling can also act as protective factors for children. While therapy can generally be helpful, it is of the utmost importance that the clinician provides affirmative and accepting practices. A clinician should be understanding of the interpersonal family dynamics as well as the broader societal factors that can affect the child's well-being. Specifically, it is important to consider the likelihood of children encountering transphobia, discrimination, or bullying. Children of trans parents also report how helpful it is to work with a clinician who is informed about all aspects of transitioning, including the legal, medical, and financial aspects.

Conclusion

Although more research is needed to fully understand the psychosocial challenges and reliance factors of children with trans parents, the current research suggests that children have similar childhood experiences to those with cis parents. It is important to understand that each experience of children of trans parents will in some respects be unique and different. While many of these children face unique challenges, research suggests that knowing a parent's identity from an early age, having a strong sense of coherence and connection among the family, and possessing adequate social support lead to more positive psychosocial outcomes for these children. Among the few studies that address this topic, the participants included are predominantly white. Further research should focus on the specific experiences of children of color with trans parents from various regions of the world.

Chronic Disease

Chronic diseases are health conditions that persist over a prolonged period and can increase the likelihood of experiencing more, and often more severe, additional health problems. Six in 10 adults in the United States have a chronic disease, and 4 in 10 adults have two or more, according to the Centers for Disease Control and Prevention (CDC). Heart disease and stroke, diabetes, cancer, obesity, arthritis, and Alzheimer's disease are some of the most common chronic diseases. In 2017, over $3.5 trillion was spent on health care, of which 90% went to managing chronic conditions. For many people, having at least one chronic health condition increases their chances of having more, or more serious, comorbid conditions. Over 10% of the U.S. population have five or more chronic health conditions. People with limited access to health care are among the most susceptible to developing chronic conditions and are most likely to have the worst outcomes from such conditions. Trans people represent one group that often experiences challenges in accessing health care—due to lack of insurance coverage, fear of discrimination in the health care environment, and social stigma.

Data on health status are sparse for the trans population—although the data available for the U.S. trans population are better than the data available in most countries. Because gender identity data are not collected systematically in medical records, most national health surveys, or any other population-level research, information about the chronic disease burden must be drawn from narrowly defined research specific to the trans community. The primary metrics of defining a public health issue, incidence and prevalence, are difficult to establish owing to the lack of data to identify the total trans population. Although some research is available, it should be considered in light of the limitations of the data used in these studies. For example, analysis of Medicare claims data indicated that trans Medicare beneficiaries experience multiple chronic conditions more often than do cis Medicare beneficiaries and have more comorbid chronic conditions. However, this research is limited to individuals who sought health care services related to their transition. Significantly, however, the conclusions drawn from Medicare analysis are supported by several state-level surveys that documented similar associations.

Both the development and consequences of chronic diseases are heavily influenced by the ability of the individual to access health care. Having a regular place to go for care, having a regular health care provider, and feeling safe with a health care provider all influence health care access. Trans people's access issues are well documented and are largely attributable to systemic discrimination, stigma, having to teach providers about trans identities and health, and lack of health insurance. Systemic structural barriers, including challenges with identity documentation, also contribute to difficulties with health care access.

Many chronic diseases, like heart disease and diabetes, result from a complicated interaction of genetics and behaviors, although in most cases, it is unknown what specifically resulted in a condition in a given individual. Behavioral factors, like smoking or eating high-fat diets, can contribute to some chronic diseases but may also be unavoidable owing to other economic and social challenges that trans people are more likely to face. Data from the 2015 U.S. Transgender Survey suggested that a third of trans people did not see a doctor when they needed to because of cost, and another nearly 25% did not see a doctor because of fear of being

mistreated. If trans people are not getting or delaying health care when they need it, they may have chronic health conditions that are going unidentified and untreated. In some cases, like diabetes or cancer, delaying care can have significant and harmful impacts.

Once identified, chronic diseases require more frequent engagement with the health care system to manage the disease(s). However, owing to the more frequent and intense health care engagement that is required for managing and treating chronic conditions, health care disparities are likely to widen for trans people who are unable or reluctant to interact with the health care system.

Trans people face other unique challenges when diagnosed with chronic conditions. Although research is sparse, some literature suggests that prolonged hormone use, which is a common aspect of transitioning, may have long-term side effects that increase risk for chronic conditions and/or increase the likelihood of adverse outcomes for those with chronic conditions.

Of note is that infection by human immunodeficiency virus (HIV), one chronic condition, continues to disproportionately affect trans people, especially trans women of color. With advances in HIV treatment and prevention, notably PrEP (preexposure prophylaxis), those who do become HIV positive can still continue to live normally while they manage HIV, like any other chronic disease, with appropriate health care access and care coordination.

Chronic diseases can also lead to more severe health outcomes when combined with another disease generated by a contagion. In light of a global pandemic, it is increasingly important to look at the impact that prior chronic disease burden will have on trans people who then become infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the virus that causes novel coronavirus disease (COVID-19). In the postpandemic world, chronic conditions will become a systemic vulnerability for all, but especially so for trans people who are already experiencing health care disparities.

Cisgender as a Term

The prefix *cis-* derives from the Latin term meaning "on this side of" or "on the same side as." Linguistically, its use in English-speaking contexts dates back to the 17th century, when it was first used as a prefix signaling relative location. In this and within the sciences, it developed in implicit relation to *trans-*, meaning "across," "through," "on the other side of," or "beyond." The term *cisgender* circulated vernacularly within some trans communities before finding its way into print by the 1990s. It gained popularity by 2010 with the increasing publication of transgender scholarship and with greater trans visibility generally. *Cisgender* was added to the *Oxford English Dictionary* in 2016 and in Merriam-Webster's dictionaries in 2017.

People began attaching *cis-* to the word *gender* in the latter 20th century to name people who are not trans. Many pointed out that normative subjects receive additional naturalization by virtue of

being unnamed, while only the marginal or deviant subject needs adjectives: *woman,* for example, was presumably white, straight, middle class, and able-bodied because if she was a person of color, disabled, poor, intersex, or transgender, she would have been named as such. Queer and feminist theory and critical race studies were among the leaders articulating the racializing processes that erase the race of whiteness and the gendering that erases the sex and sexuality of straightness, just as feminisms decades earlier drew attention to the erasures and mystifications behind the universalizing use of the term *man*.

Gender scholars explain that gender is a social organizing principle and that all persons are constituted within the hierarchies, violences, and pleasures of the requirement to "have" and "be" a single, unchanging gender. Some scholars have found it useful to name those who are not transgender. One purpose of the term *cisgender* was to denaturalize what otherwise goes unnamed as the *natural* gender, when in fact cisgender depends on labor, construct, coercion, and reward. Some people suggest that the term *cisgender* is useful for naming the privileges associated with being perceived to be aligned with the sex/gender one was assigned at birth. Use of the adjective *cisgender* can also call attention to the existence of gender diversity in contexts that otherwise erase trans presence when the differential treatment accorded to, for example, cis and trans women must be noted.

Critiques of *cisgender* abound. Decolonial, queer of color, Indigenous, trans feminist, and nonbinary perspectives point out that *cis-* circulates within compulsory binary logics and thus perpetuates the same discriminatory violences that trans communities sought to dismantle with adoption of the term *transgender* in the late 1980s. Binary logics obscure the complex personal, social, and physiological embodiments that all persons carry. In everyday parlance, *cisgender* reinforces assumptions that if someone does not appear to be trans, they are cisgender and enjoying the unearned privileges that accrue to cisgender people. To wit, everyone is cisgender unless we know they are trans. Scholars have noted that this assumption erases trans people and denies the complex embodiments and the fluidity of gender that are possible in all people's lives. More fruitfully, we might explore the ways cisgender privilege arises when anyone is passed as cisgender, regardless of their past, present, or future identification and embodiment.

Scholars and popular critics have objected to the narrowing effects of the cis–trans binary. Various trans and queer communities work to expand the parameters of trans, recognizing diversity around issues such as degree of "cross-gender" identification, lived gender expression, and desire for bodily modifications. In contrast, the term *cisgender* has received increasing clarification and reduction: Specifically, *cisgender* is used to name the condition in which one's gender identity and sense of self are congruent with the sex/gender one was assigned at birth. In common use, the term also implies that cisgender subjects conform to dominant norms and expectations associated with anatomically defined sex/gender. One trap of this binary logic is that *trans* then depends on positing cisgender as an unchanging subject that cannot also be trans and/or living with invisible body/mind variations such as intersex and disability.

Many people have argued that the notion of being "congruent" with sex assigned at birth grossly simplifies the vast range of ways that people experience gender identity and norms. Bodily morphologies vary infinitely, and many who do not identify as trans navigate chosen and unchosen gender nonconformities. Use of *cisgender* also receives critique by trans exclusionary radical feminists (TERFs), who insist that all persons *are* ontologically and socially exactly and only the sex/gender to which they were assigned at birth and that therefore trans women are not women; paradoxically, TERFs also claim that trans people and the institutions that support them have eliminated gender diversity for assigned-at-birth females, making it impossible for assigned-at-birth girls to know themselves as tomboys, lesbians, and butch women.

Analysis of gender diversity and complexity should recognize racialization, ableism, nationalism, and other forms of institutionalized violences that shape most people's lives. It is a fact that most trans people face seemingly endless barriers and violences within most social institutions. However, very few people have been seamlessly passed as normatively cis, and thus we might see cisgender not as a thing many people are but rather as a possibility to which few have access and all must labor to approximate.

Cis is not merely a *gendering* logic. Binary and normative gender structures arose and continue via white supremacist, capitalist, and ableist colonization, enslavement, and experimentation that have objectified, harassed, assaulted, misidentified, incarcerated, and murdered countless humans in North America and around the globe. These traumas are perpetuated in the reduction of humans to a cis–trans binary. Trans, feminist, nonbinary, intersex, crip, decolonial, and antiracist critiques suggest we resist the facile assertion that people who appear to be nontransgender have stable access to the privileges of normativity.

The separation wrought by the cis–trans binary has necessitated new vocabularies that reject binary opposition. The singular pronoun *they* circulates widely with many meanings and, at its most general, means *not* cisgender. Nonbinary and genderqueer, and (in Indigenous communities) elaborations of two-spirit and language-specific terms all resist the failures of cis–trans binaries.

Cisgenderism

Cisgenderism is an umbrella term for systemic oppression that treats some people's understanding of themselves as invalid. Cisgenderism involves concepts, language, and behavior that problematize people's own definitions and classifications of their genders and bodies. While cisgenderism may manifest as individual instances of prejudice and discrimination, it is rooted in systemic practices and ideology. Cisgenderism can affect all people, regardless of gender identity or expression, although people are more likely to be targeted for cisgenderism in countries and regions where external authorities rather than people themselves make official classifications and where such authorities disagree with people's own classifications of their genders and bodies. Consequently, people who have a trans experience, identity, history, or expression are more likely to be targets for cisgenderism in many societies. This entry discusses the field of cisgenderism studies, which examines the effects of distinct forms of this oppression and aims to reduce it through critiquing and challenging systems, institutions, and societal norms.

The cisgenderism framework has been influenced by work in the fields of critical disability studies as well as critical racism and ethnocentrism studies. Both critical disability studies and the cisgenderism framework critique the external application of labels that the people to whom such labels are applied find stigmatizing or inaccurate. The cisgenderism framework also emphasizes the critique from critical racism and ethnocentrism studies that categories such as "trans," which are developed in one cultural context, cannot be presumed applicable to another without evidence to that effect. For example, many societies around the world recognize more than two traditional genders (e.g., five genders in Bugis society in Sulawesi, Indonesia); some societies assign gender categories based on nongenital physical attributes (e.g., a birthmark resembling that of a deceased ancestor's birthmark, as documented in a Thai family); some societies in Asia and the Americas recognize social gender status changes on the basis of self-reported dreams, public declarations, or community rituals; and some African and Asian societies treat shifts in gender category across the life span as normative and typical rather than "trans," "variant," or "nonconforming." Gender in some societies varies by the particular behavior or context, not by fixed attributes of the person. Some scholars have critiqued the concept of "gender" itself as ethnocentric and inaccurate when applied to these societies.

In contrast, the culturally specific notion of "trans" in contemporary settler-colonial U.S. and

European societies is based on culturally relative assumptions that there are only two valid genders, that gender is determined by external genital appearance at birth, and that "trans" people go from one to the other of two valid options. Such cultural assumptions can lead to forms of cisgenderism such as retroactive misgendering (in which people's pasts are described using language that invalidates their current gender self-identification or discloses their gender history) and coercive queering (in which self-identified heterosexual people who have "trans" life experiences or intersex characteristics are conflated with lesbian, gay, bisexual, or queer people).

Cisgenderism can take the form of pathologizing (treating a person's gender(s) or lack thereof as disordered), misgendering (disregarding the way a person understands and classifies their gender(s) or lack thereof), marginalizing (treating a person's gender(s) or lack thereof as strange or exceptional), coercive queering (assuming a person falls under an "LGBTQIA+" umbrella when they may not identify or live that way), and objectifying (describing a person by referring to some aspect of their presumed anatomical or physiological characteristics, especially in situations where other people are called simply "women" or "men").

Regardless of intentionality, these forms of cisgenderism function in ways that harm people. Pathologization can exacerbate depression and also create barriers to seeking mental health treatment. Marginalization, meanwhile, can cause strain on individuals and families. For example, the insistence on a gender binary leaves nonbinary people subject to ridicule, including hate crime victimization. For another example, a North American study found that when a person publicly describes themselves as trans, family members often perceived this classification as a loss, because it diminishes their access to privileges that are tied to belonging to the dominant group.

History

The term *cisgenderism* comes from the Latin prefix *cis,* meaning "on the same side as," and *gender,* from the Latin *genus,* meaning "kind" or "type." Y. Gavriel Ansara and Peter Hegarty introduced the concept of cisgenderism to the psychological and sociopolitical literature in 2012, and their subsequent pan-disciplinary research along with related research initiated the broader field of cisgenderism studies.

The term *cisgenderism* emerged after the term *cisgender* and was initially used by trans scholar Julia Serano as a synonym for a person who would be classified as cisgender. Subsequently, Ansara and Hegarty redefined the word as an "ism." Unlike prior use of this term, Ansara and Hegarty's model critiques rather than endorses the idea that all people can be classified as either transgender or cisgender (i.e., "not transgender"). In fact, the notion of a cisgender–transgender binary may itself be viewed as cisgenderist, as this binary assumes that people described as "cisgender" meet certain standards with regard to "matching" their assigned sex and that people described as "transgender" change from this initial status to another. Such a binary neglects the experiences of people whose experiences and bodies differ from these limited expectations.

Classifying cisgender and transgender is often complex, and the distinction is often ultimately unresolvable. Difficulties may present themselves on the basis of science (given, for example, the existence of intersex people), culture (given, for example, the existence of third-gender roles and people who deliberately assert themselves as living outside the roles specified by their culture), and each person's individual experience (given, for example, people whose felt or asserted identity is independent of a desired or completed transition to a new gender role or lack thereof). Those excluded by this binary may include, for example, people with intersex characteristics; women who would be classified as cisgender but who experience misgendering as a result of stereotypically "male" facial and body hair associated with polycystic ovarian syndrome or as a result of "boyish," less curvy figures; cisgender people who live in their assigned gender category in everyday life but who participate in drag or crossdressing; people with nonbinary genders in societies that recognize more than two valid genders; and people in societies that recognize changes of gender as culturally normative coming-of-age experiences. Critiques of cisgenderist ideologies must therefore also challenge the idea that every person can be classified as either cisgender or transgender.

Conceptual Distinctions

In discussions of harms caused to people with marginalized genders and bodies, especially trans and intersex people, it is common to see words like tran*sphobia, cissexism, genderism,* and *cisnormativity.* However, these terms are not identical to what is expressed by *cisgenderism.*

Transphobia describes prejudice against trans people. It presumes that target individuals or populations are classified, self-identified, or perceived as trans. Therefore, transphobia does not easily explain or describe effects (whether intentional or unintentional) on people who may not fit within "transgender." The inclusion of the word *phobia* suggests that the term primarily describes manifestations of personal prejudice or hostile acts rooted in emotion. Consequently, it cannot describe ideology adequately or explain how systems and institutions delegitimize people.

Cissexism refers to prejudice or discrimination against people who are perceived by others as trans, regardless of whether these perceptions are accurate. This term accounts for effects on people of cis experience or who do not neatly fit into a cisgender–transgender binary. However, it is limited insofar as it only applies to cases in which the person is *perceived* as trans. The term also implies that the perpetrator of the prejudice or discrimination has a personal attitude or ideology that is tied to a concept of what it means for someone to be "transgender."

Genderism describes an ideology behind anti-trans attitudes, including prejudice against those who change their gender category or who challenge gender categories altogether. Like *transphobia,* however, it does not easily account for the experiences of and effects on people who are not necessarily classified, self-identified, or perceived as "transgender."

Cisnormativity describes the presumption that most people fit, or want to fit, within the norms of their culture's gender binary and the assumption that most cultures have a gender binary. The notion that everyone is by default cisgender is one manifestation of cisnormativity, as is the idea that if someone is trans, they must attempt to fit into the gender binary. Cisnormativity involves ignoring or devaluing how people challenge gender norms and may dismiss the validity of trans experiences and identities. Cisnormativity is closely related to cisgenderism and can be classified as a type of cisgenderism.

By contrast, *cisgenderism* encompasses an overarching oppressive ideology across a range of intentions, classifications, and identities. Cisgenderism can describe systems, values, and actions that occur in varied cultural contexts, including hostile or benevolent acts and intentional or unintentional acts. Thus, transphobia, cissexism, and genderism could be conceptualized as forms of hostile cisgenderism. In contrast to approaches that treat "cisgender" and "transgender" people as distinct classes of people, the cisgenderism framework views the notion that all people fit into a transgender–cisgender binary as an essentializing form of cisgenderism. Such approaches exclude a variety of people's experiences of discrimination and delegitimization as discussed above.

Cisgenderism Research

Together with the minority stress model, the cisgenderism framework underpins a number of significant studies in trans health. Since 2012, researchers have addressed how cisgenderism operates in a variety of contexts. Whereas the transphobia paradigm focuses primarily on people's internal attitudes, motivations, and prejudices, the cisgenderism framework prioritizes systemic forms of injustice such as institutional support for inequities.

Ansara and colleagues have explored how cisgenderism affects the fields of child and adolescent mental health, medical services, general mental health, aged care, and family therapy.

Ansara and Hegarty's 2012 article, in particular, has led to substantive changes in the language about trans health, including within the World Professional Association for Transgender Health (WPATH), one of the most influential global professional bodies working in the field. By highlighting and articulating the role of language in health access barriers and health policy, Ansara and Hegarty's research is recognized as having made lasting improvements to how people with trans lived experience are conceptualized, described, and therefore treated by health professionals around the world.

Damien Riggs, Y. Gavriel Ansara, and Gareth Treharne (2015) examined the mental health experiences of trans Australians. They identified three factors that appear to be critical to determining

outcomes: discrimination, access to hormones and/or gender-affirming surgery, and community connectedness. They proposed a model identifying how cisgenderism and decompensation (the processes through which cumulative effects of stressors may lead to poor mental health) interact to negatively affect people's mental health.

Jama Shelton used the cisgenderism framework to interrogate and identify systemic oppression that hindered trans people's access to homeless shelters; Michaela Rogers explored the role of cisgenderism in the cases of domestic violence and abuse reported by trans and/or nonbinary people. Rogers documented how cisgenderism in the forms of identity abuse, misgendering, and pathologizing underpinned experiences of domestic violence, highlighting the importance of the cisgenderism framework for investigating the relationship between systemic and personal experiences of oppression.

The field of cisgenderism studies aims to identify and reduce cisgenderism across all dimensions of life. Ansara and Hegarty highlighted how common research practices can result in misgendering: assuming people's genders based on their given names, visual appearance, or culturally variable "clues"; conflating gender designations with assigned "sex" categories and bodily characteristics; assuming people's self-identified gender matches or should fit with a particular assigned sex category; failing to document how researchers determined participant gender; excluding nonbinary people by failing to include a nonbinary gender option in items intended to collect demographic gender; misgendering nonbinary people by using binary pronouns and descriptors to characterize them; and excluding nonbinary people as "outliers" when conducting statistical analyses. Professionals can reduce cisgenderism by avoiding these practices.

Cisnormativity

Cisnormativity is the presumption that most people do, or should, conform to the norms about gender assignment in their society. It may manifest as the assumption that everyone by default chooses to accept the gender that their parents or societal

authorities have assigned to them, or the assumption that all cultures by default have a gender binary that is similar to or based on U.S. or Western European cultural norms. This may include the use of marked language to describe people who do not fit a culture's gender binary. For example, cisnormative behavior could involve referring to people as "trans women" or "trans men," where other people are simply described as "women" or "men." It may also rest on the premise that, if someone is transgender, they must still fit into their society's gender binary; for instance, trans women should be especially "feminine" and not "butch" or "masculine," and trans men should be especially "masculine" and not "femme" or "feminine." Cisnormativity ignores or devalues the ways in which people individually express their gender or actively challenge gender norms, and it may dismiss the validity of trans experience and identity altogether.

The term comes from the Latin prefix *cis,* meaning "on the same side as," and the noun *gender,* from the Latin *genus,* meaning "kind" or "type," as opposed to *transgender,* which comes from the Latin prefix *trans,* meaning "on the opposite side," and Latin *genus.* The concept of cisnormativity relies on an underlying assumption that people can be divided neatly into a binary of cisgender versus transgender—a notion that has been critiqued in recent years. Cisnormativity is itself a form of cisgenderism, an ideology that treats some people's genders and bodies as less legitimate than others and challenges how people define and understand their own genders and bodies.

Development of Theories of Gender

Societies across Asia, Africa, and the Americas have long had more than two traditionally recognized genders, and each society has its own approach to gender. For example, there may be several genders like those of the Bugis people of Sulawesi, Indonesia, who have five distinct genders. Gender may not be a central organizing principle in other societies. For example, Oyèrónkẹ́ Oyěwùmí describes how a person's role, which has been classified as "gender" by colonial scholars, can change entirely depending on the context of a social interaction and explained that the concepts of "woman" and "man" were not fundamental categories of human difference in Yorùbá society prior to colonization. Oyèwùmí critiqued biological essentialism in Eurocentric feminist notions of gender.

Unfortunately, modern academic theories of gender have largely ignored thought from outside of English-speaking and European traditions. Within the Greco-Roman tradition that influenced European thinking, Galen's (b. 129 C.E.) theory of bodily humors determined people's views on what constituted a man or a woman. This approach differs from many contemporary views, as Galen held that when bodily humors changed, people would then metamorphose into having the physiological characteristics of another binary gender. It is important to note that Galen's ancient Hellenistic approach, which was dominant in Europe until the 1500s, did not differentiate clearly between gender and sex—the latter of which, in the English-speaking sense, is a 20th-century development. In many European languages, there are no traditional words that can be readily adapted to differentiate these two concepts. Outside of Greco-Roman thought, there were, and still are, many societies in which shifting between gender/sex categories could be achieved through self-declaration or public ritual. Such societies place varying degrees of importance on social and physical aspects of gender/sex.

From the 1800s to early 2000s among colonial Western European and U.S. thinkers, the term *gender* was often used synonymously with *sex* in a cisnormative manner, with people defined as having varying degrees of "masculinity" and "femininity" in their natures, mannerisms, preferences, and behaviors. These concepts were often constructed as universal truths but have in fact been locally and culturally defined. For example, colonial anthropologists initially regarded men of the Aka people of the western Congo (referred to today as the Nuer people of modern Ethiopia and Sudan) as "feminine" because of their more extensive childcare duties compared with colonial men's norms. However, this approach is ethnocentric and colonizing, as their own communities do not view these men or their childcare responsibilities as womanly or feminine. Such duties were, and are, simply part of their societal roles as fathers and grandfathers.

From the 1970s, some feminist scholars such as Sandra Bem conceptualized sex as biological

and gender as a separate social and psychological concept. Although Bem's research provided a framework for "masculinity" and "femininity" as independent, co-occurring variables, this approach also obscured the socially constructed and culturally variable foundations of "biological sex." In the 2000s, some researchers created more complex frameworks for understanding sex and gender. For example, David Perry and colleagues developed a multidimensional view of gender, while Charlotte Tate and colleagues made clear distinctions between facets of gender such as birth-assigned category, self-assigned category, gender role expectations, and presentation of self-assigned gender category. Y. Gavriel Ansara and colleagues later conceptualized self-designated gender (a person's self-concept) as distinct from gender assigned at birth (whether based on external characteristics or the surgically altered assignment of intersex people).

Sexuality, sexual orientation, and facets of gender have often been conflated; however, a person of any gender or gender history may experience a range of sexual orientations and sexualities. Associated with cisnormativity is the concept of heteronormativity (the presumption that individuals are, or should be, heterosexual), such that the unmarked category "people" is presumed to describe only people who are of both cisgender and heterosexual experience.

Cisnormativity is widespread and can negatively affect "cisgender" people who do not conform to their culture's expectations around gender roles. The field of gender studies has been attacked by socially conservative authorities, including the Vatican, and teaching or promoting gender studies curricula has been criminalized in former Soviet countries such as Russia, Hungary, Poland, and Romania as part of an "anti-gender movement." In recent years, a form of feminism known as trans exclusionary radical feminism (TERF) has contained cisnormative arguments similar to those of social conservatives, promoting the vilification of people with a trans lived experience in the guise of "gender-critical" feminism. This TERF approach has been used to promote discriminatory legislation, such as prohibiting equal access to public toilets and the right to be treated in accord with one's gender in workplaces, accommodation, and public venues.

Sources of Cisnormativity

While it appears that the majority of people who self-identify as women have vulvas/vaginas, and the majority of people who self-identify as men have scrotums/penises, available evidence documents that this is not a universal truth. This assumption relies on the erasure of people of trans experience and intersex people—that is, people born with bodily characteristics that are not considered stereotypically female or male according to contemporary medical norms. This unfounded expectation is thought by some scholars to be the source of cisnormativity.

Although the concept of cisnormativity may imply a universal set of binary gender norms, what constitutes "cisnormative" behavior varies depending on the gender norms in place within a given society. For example, in some societies, having only "woman" and "man" as gender categories would not be cisnormative; however, it is less clear in societies that offer more than two traditional gender options how cisnormativity would apply. Thus, the concept of cisnormativity may in itself contain ethnocentric assumptions.

Consequences of Cisnormativity

Most of the research in the area of transgender health has been based on the minority stress model and relies on cisnormative concepts, in contrast to research from 2010 onward that has relied on the cisgenderism framework to critique cisnormativity. The cisgenderism framework is a paradigm for identifying and challenging systemic oppression that treats some people's understanding of their genders and bodies as invalid or problematic. Cisnormativity has negative physical, mental, and socioeconomic effects, particularly on trans people, who are explicitly excluded from the supposed norm.

Cisnormative beliefs and practices devalue or ignore the diverse ways in which people navigate gender norms, which may include dismissing the legitimacy of transgender experience. Cisnormativity can thus make trans people vulnerable to exclusion or mistreatment. For example, trans people in some jurisdictions have been required to have a mental health diagnosis of gender dysphoria in order to access gender-affirming

medical services. From 1980 on in Germany, the Transsexuellengesetz (Transsexual Law) has required people to receive a mental diagnosis as a precondition for changing their gender on government-issued identity documents. In 2018, after previously requiring mandatory sterilization before permitting people to change their legal gender designation, Sweden became the first country to provide compensation for these coerced procedures.

While these medical requirements are in themselves a manifestation of cisnormativity, they have also forced people to interact with systems further steeped in cisnormativity. The 2015 U.S. Transgender Survey found that 13% of respondents had had at least one health professional or religious adviser attempt to stop them from being trans. This experience was correlated with higher rates of psychological distress, attempted suicide, running away from home, and homelessness. Pressure from professionals and family members as well as difficulties finding employment, rather than changes in their sense of self, were related to 8% of respondents (mainly trans women) having "detransitioned" at some point, usually temporarily. One-third of respondents reported at least one negative health care experience in the past 12 months, including one quarter having to educate health care providers about trans health, 15% being asked inappropriate questions, 8% being refused treatment related to trans health, and 3% being refused treatment unrelated to their trans status.

Combating Cisnormativity

Annalisa Anzani and colleagues (2019) explored how microaffirmations operate within psychotherapeutic contexts, finding four levels of increasing affirmation: the absence of microaggressions, acknowledging cisnormativity, disrupting cisnormativity, and seeing authentic gender. The first two levels represent more passive ways to reduce cisnormativity, whereas the latter two require a more active effort.

Awareness of cisnormativity and other forms of cisgenderism is a starting point. By recognizing the potential for microaggressions, one can abstain from committing them. Additionally, acknowledging the cisnormative context and identifying opportunities for performing microaffirmations can help the people who are experiencing the negative effects of cisnormativity to feel validated.

Examining systems for specific instances of cisnormativity can be an effective way to reduce cisnormativity and other forms of cisgenderism. For example, the widespread practice of limiting gender options on forms to "male" and "female" and imposing marked gender categories such as "trans man" or "transgender woman" on people are instances of cisnormativity, as they assume gender self-designation should be linked to sex assignment within a culturally specific binary. Such practices exclude people whose assigned sex at birth and self-designated gender are erased by cisnormative expectations, people whose gender and sex identities are not considered a "match" within cisnormative classification systems, and people who have no gender or who have nonbinary or plural genders. Recognizing a person's self-designated gender, regardless of their external appearance, is the final step in Anzani's model. It also requires the most effort and active cognitive negation of cisnormative expectations.

Regardless of the degree to which an individual is able to challenge their own cisnormativity, it is important to challenge systemic forms of cisnormativity whenever possible. Doing so may prevent or minimize harm that can occur as a result of cisnormative expectations and improve health and socioeconomic outcomes for these populations.

Citizenship

Trans citizenship concerns the rights and responsibilities that trans people have across a range of different social spheres, including the law, politics, health care, cultural representation, and the wider society. The concept of trans citizenship allows us to think about universal trans rights, such as the right for a trans person to determine their identity, to have choices about their body, and to live as an equal citizen to cisgender (cis) people. It also enables us to think about the issues facing specific groups of trans people, such as trans people of color, trans people who are nonbinary, and/or trans people living in a country where violence against trans people is particularly severe.

Ideas of trans citizenship were developed in the early 2000s in order to move away from approaches to trans that pathologized gender diversity, exoticized it, or framed it primarily in terms of activist struggles. That said, activist struggles and agendas were, and continue to be, central to trans citizenships. Activist interventions informing trans citizenship include everything from activist lobbying to gain or protect legal standards to media representation and challenges to hegemonic social movements that are prejudiced against trans people (such as anti-trans cis women who frame themselves as feminists). Overall, the issues raised by activists can be examined and addressed via the framework of citizenship.

Citizenship can be defined as a set of rights and duties that determine whether, and how, we are members of a particular society and what social benefits we can expect to have access to. It is a politically neutral term in the sense that it can be used to support trans rights agendas, moving debates away from problematic areas, such as the pathologization of trans identities, and toward approaches that support trans people as members of society and as having legal protection, access to welfare and health care, social visibility (if wished), and a variety of other privileges that many cis people take for granted. However, if someone is not a national of a particular society, then they may be unable to access the most basic of citizenship rights, such as the right to life. From an intersectional perspective, trans citizenship is shaped by other social forces that affect individual trans people, such as immigration policies.

Key Aspects of Trans Citizenship

The fundamentals of citizenship were developed in the 1950s and consist of legal citizenship, political citizenship, and social citizenship. Legal citizenship is crucial for trans people—and it is still lacking in many countries, including legislation to support gender recognition and to punish hate crimes

against trans people. Trans people have become much more visible politically over the past several decades, but their small overall numbers make electoral democratic representation a challenge, and not all trans people are able to (or wish to be) be out as trans. Social citizenship levels vary widely across different countries, but persecution and bigotry are still common; hence, there is a strong ongoing need for basic trans citizenship in general.

Feminist citizenship scholars provided an important challenge to mainstream citizenship (legal, political, and social), arguing that citizenship is not only about the public sphere (such as representation in electoral politics) but also about the private sphere, and women are often excluded from full citizenship. Trans people, including trans women, share this problem of exclusion from full citizenship, and private issues (such as access to gender reassignment surgery and to reproductive technologies) are of key importance to their citizenship claims. Feminist author Nancy Fraser provided the notions of recognition versus redistribution. Trans recognition concerns the acknowledgment and inclusion of trans people in, for example, equality and diversity statements, rainbow flags, and news coverage. However, it does not address the structural marginalizations that trans people can face—for example, employment discrimination and a lack of resourcing for trans-specific health care. These can only be addressed by redistribution—changes to the economic underpinnings of the labor market and the distribution of money within society (through, for example, welfare provision). Although the ideas developed by feminist citizenship scholars remain important, many cis feminists have to date been unable to move beyond gender binarism rooted in biological essentialism, making it especially important that trans citizenship is further developed. There is a need for cis feminists and others to apply basic tenets of feminism such as equality, bodily autonomy, self-determination, and antioppressive reflexive practice to "gender-critical" and anti-trans politics, as well as to the field of trans citizenship. Intersectionality theory amply demonstrates the many social forces that crosscut cis and trans women's lives, including sexism, racism, and socioeconomic inequalities, meaning that sex/gender-based biologically essentialist positions (such as "gender-critical" approaches) are ideologically and theoretically untenable. Right-wing persecution of trans people is on the rise internationally, and there are indications that anti-trans and gender-critical feminisms are lending support to media scapegoating and violence toward trans women (for example, in the United Kingdom).

Other approaches to citizenship can be used to support trans citizenship, including intimate citizenship, which emphasizes the importance of bodily autonomy and the right to relationships and sexual expressions with chosen people. For trans people, the right to decide what to do with one's body (whether to have surgery or not, for example) is very important. For some trans people, including nonbinary people, relationship forms may be other than the heteronormative form of male–female, and intimate citizenship is flexible enough to support and accommodate this variation. Coming from a different angle, health citizenship can be important for trans people, many of whom have ongoing health care needs (for example, access to hormone treatment). Health citizenship includes not only the right to health care but also related mechanisms for involvement in determining the type of health care provided (such as inclusion in consultations about health care policy). A further approach is children's citizenship; indeed, the rights of non-normatively gendered children is a particularly challenging area. Children in general lack full citizenship rights, and trans children (and indeed any children who challenge norms about gender) face increased levels of bullying, mental health difficulties due to discrimination and abuse, and sometimes familial rejection. The issue of bodily autonomy is especially pertinent here, as a child or young person may be pushed to decide what (binary) gender they want to be and undertake irreversible treatment before they are really ready to do so but, conversely, may be blocked from access to treatment that they really need.

Concluding Thoughts

Overall, citizenship provides a flexible way of thinking about trans people's rights and involvement in society. Importantly, it lets us think about the rights claims that trans people share, such as the right to personal safety and to recognition of the gender they identify as (universalist approaches).

However, it also allows us to focus on specific issues that some trans people might face and others might not (particularist approaches). For example, nonbinary people might be more likely to hide their identities owing to the lack of legal recognition for nonbinary identities. There is a need for the development of particularist approaches to trans citizenship, focusing on specific marginalized and overlooked groups. These include in particular those groups of trans people who are socially marginalized for reasons other than/in addition to being trans, for example, due to ethnicity, ability, socioeconomic class, sexual identity, nationality, or location. Some work is available; for example, there is some work on trans sex workers in Brazil and citizenship issues. However, there is space for a lot more work to be done about intersectional and international trans citizenships.

Classroom Experiences, Higher Education

Classroom experiences have a major impact on trans students' academic and social well-being. A positive classroom environment is one in which students feel a sense of belonging, trust each other, and feel encouraged to take on challenges or take risks to ask questions. For trans students, a welcoming classroom experience is particularly important for them to feel safe, respected, and supported. Trans students are more likely to flourish and express themselves freely when they experience a classroom that explicitly uplifts them with emotional support, relevant content that demonstrates empathy, clear learning objectives with specific feedback, and opportunities to develop social skills and strategies to help them succeed. In fact, when trans students have affirming classroom experiences, they are more likely to pursue high-impact educational practices, which have positive relationships to retention and graduation.

Unfortunately, however, in many colleges, trans students commonly report feeling unsafe in the classroom as a result of discriminatory learning experiences. A negative classroom climate can feel hostile, chaotic, and unwelcoming for students. Negative classroom environments have a detrimental effect on trans students, limiting their ability to wholly express or recognize their full selves. For example, when trans students do not have their identity, names, and pronouns respected, it inherently discourages community, openness, and learning. A negative classroom environment may adversely influence students' sense of self-confidence, damage relationships with peers, and negatively shape their mental health, academic success, and socialization in college. Particularly in disciplines that are accredited (e.g., nursing, education) or have more positivistic curricula (e.g., science, technology, engineering, mathematics), trans students may feel particularly excluded, given the restrictive modes and content of teaching that do not fully recognize the fluidity and social construction of gender.

Changing the Paradigm

Faculty members, instructors, or anyone who is in the position of authority (including students) must create an affirming classroom characterized by mutual respect to foster positive classroom experiences. To promote better learning, instructors need to develop environments where students feel safe asking questions and contributing to discussions. Additionally, the work of creating a better classroom climate should not be based solely on good intentions. There are a number of preventive and protective measures that college administrators and faculty can take to promote positive learning experiences among trans students. For example,

faculty can organize dialogue groups to facilitate community and better understanding among students and assist them in supporting one another through their learning and development. Providing specific instructions on how to positively interact in the classroom can create a culture rooted in the inherent worth and dignity of all students while also promoting an enriching space for learning. Academic administrators and faculty may create inclusive language and communication policies to promote inclusion and equity. Such policies should clearly state classroom expectations for respecting names and pronouns that students use for themselves, avoiding unnecessarily gendered language, and procedures for reporting discrimination experienced in the classroom.

Administrators can offer training sessions for faculty and students on ways to affirm people across genders, foregrounding trans student experiences and narratives. Such trainings may proactively help reduce hostile classroom incidents toward trans students and prevent assumptions about how to best engage, communicate with, or help trans students. These trainings should center on the needs of trans students while also educating faculty and students about genderism and other systems of oppression that shape students' experiences in class. Providing advice and tools for promoting inclusivity and equity is important, as is helping instructors understand how their assumptions of gender and trans people shape their classroom.

Additionally, colleges can create an LGBTQIA+ campus center to support faculty in developing trans-inclusive classroom cultures. At many colleges, trans students do not have the opportunity or the access to administrators to advocate for themselves. An LGBTQIA+ center can support the needs and voices of trans students while also holding institutional entities responsible for promoting warm and inviting campus environments. Although a designated center to assist trans students is an important component to promoting positive campus experiences, the sole responsibility for educating faculty cannot rest on LGBTQIA+ centers. Institutions are encouraged to embrace a holistic approach to broadly promoting equity and inclusion across all functional areas, including college classes.

A number of structural changes can promote more inclusive classroom experiences for trans students. For example, administrators should develop a policy that enables students to change their name and gender marker on institutional records and to include their pronouns on class rosters. College administrations may consider designating a specific space or person for whom trans students can go to seek support, such as an LGBTQIA+ center or trans student advocate. If trans students know that there is a specific space or person on campus to provide guidance, they will feel more welcomed and affirmed in classrooms and beyond. In addition, all campus buildings should include gender-inclusive restrooms so that trans students do not have to compromise their safety, comfort, and health for the sake of learning. All students deserve to be in conditions that respect their identity and their dignity.

As numerous observers and activists have noted, creating a positive classroom experience for trans students is everyone's responsibility and requires a concerned commitment to gender equity among students, faculty, and administrators within and outside of the classroom. Affirming classroom spaces campus-wide will foster trans students' academic performance and promote overall success.

College Graduate Students

Graduate students face unique stresses, particularly those who are members of one or more marginalized groups (e.g., sexual minority graduate students; graduate students of color). For example, in addition to navigating the typical challenges of academic work and low wages, minority graduate students face challenges in terms of accessing mentors and support networks that share, or are at least sensitive to, their identities. Trans graduate students, in particular, face challenges with regard to mentorship and social support, given the paucity of out trans faculty members and mentors on most university campuses. They also face other challenges related to applying to graduate school, choosing a graduate program, determining appropriate career paths, and searching and applying for jobs.

In applying to graduate school, trans prospective graduate students consider not only the rigor, reputation, and cost of various academic programs but also the relative safety of the community and state in which each program is housed. That is, like all prospective graduate students, they consider the location of the program—but with additional considerations related to state laws and policies (e.g., related to nondiscrimination protections for trans people), as well as community climate and resources (e.g., Is there a visible LGBTQIA+ and specifically trans community? Are there clinics that provide hormone therapy and/or trans-competent mental and physical health professionals in the area?). Trans prospective graduate students also consider university-specific factors, including indications of trans-inclusiveness in application or university materials, presence of trans-inclusive or trans-competent curricular offerings and faculty research profiles, and LGBTQIA+ and specifically trans visibility in university and departmental resources and webpages (e.g., presence of an LGBTQIA+ resource center; explicit acknowledgment of trans people as members of the campus community). They may also consider access to trans-inclusive health care coverage. Trans prospective graduate students also consider whether and to what degree potential mentors in a given program or department are, or appear to be, informed and competent regarding trans or at least LGBTQIA+ issues and identities.

In graduate school, trans graduate students must navigate issues of visibility and outness. For example, they must decide, on an ongoing basis, whether to share their gender identity with others and/or correct others (e.g., faculty members, peers, staff members) if they are misgendered. Nonbinary graduate students, in particular, may face challenges in this regard, since their gender identities are generally even more poorly understood and less likely to be validated as compared to binary gender identities (e.g., trans man, trans woman). Speaking up and correcting a faculty member, or pointing out the pervasiveness and destructiveness of the gender binary in coursework, fieldwork, or university materials, carries significant risk for trans students. They recognize that by speaking up, they may be placing their future in jeopardy, insomuch as a faculty member may be less willing to write a (good) letter of recommendation if they are viewed as a troublemaker or "problem" student, for example. Likewise, they risk alienating a future resource for networking and job advice when they correct or confront a faculty member's ignorant or explicitly transphobic comments or actions.

There is evidence that trans graduate students who have affirming mentors tend to report better well-being and to progress more quickly and easily along in their intended career pathways. Additionally, trans graduate students who study in certain fields (e.g., the humanities, the social sciences) may struggle less than those studying in fields that are deeply rooted in the gender binary (e.g., STEM fields). Likewise, trans graduate students who are able to access trans-inclusive and trans-competent physical and mental health care tend to report that this is important to their academic, social, and emotional well-being. Additionally, trans graduate students who have access to LGBTQIA+ and trans resources/supports on campus that are graduate student specific (as opposed to being geared to the needs

and developmental stage of undergraduate students) tend to report greater satisfaction with such resources.

When considering various career paths and applying for specific jobs, trans graduate students often consider the relative trans-friendliness of each potential path. They may consider, for example, whether it will be possible to be out as trans in a job, whether they will be accepted as trans in a job, and whether the job offers trans-inclusive health insurance. Trans people may pursue some occupations over others because of the relative safety of those fields. For example, they may shy away from government jobs or jobs with young children because of fear that their trans identity will come under scrutiny in ways that could be dangerous or simply very uncomfortable. In applying for jobs, trans people navigate the possibility that "mismatches" between their names and gender markers on different documents and publications across the various stages of their academic journey may act as a tipoff for their gender identity. In turn, they must decide whether to address such inconsistencies directly or seek to resolve and eliminate discrepancies in advance of their job seeking.

College Undergraduate Students

Trans students in general have a more positive experience in college today than ever before. But this improvement is relative and remains uneven. The extent to which trans students continue to frequently encounter institutional and individual discrimination depends on a number of factors, including the type of college they attend, their academic major, the cocurricular activities in which they participate, and personal characteristics, such as how visible their transness is to others, their particular gender, and other aspects of their identities. Students who are known or perceived as trans, especially trans women and nonbinary individuals, often have a much more negative experience because colleges largely remain rooted in and continue to foster a binary understanding of gender and fail to challenge the anti-trans prejudice that is all too common among cis students, staff, and faculty. At the same time, trans students who also belong to other minoritized groups, such as trans students of color and trans students with disabilities, experience multiple marginalizations and often feel that at least one aspect of their identities is unacknowledged or unwelcomed in most spaces on campuses. In addition, some types of schools, such as community colleges, conservative religiously affiliated institutions, historically Black colleges and universities (HBCUs), and historically women's colleges, and some microclimates, such as athletics, fraternities and sororities, and residence halls, present unique challenges to trans students. Thus, even though trans Gen Z students (i.e., students born in the mid- to late 1990s through the early 2010s) receive greater support than previous generations of trans students, they cannot count on

feeling included and appreciated at all institutions and in all institutional environments.

How College Experiences Vary by Aspects of Identity

The experiences of trans students in higher education are greatly affected by a number of individual factors, including their academic interests, campus connections and involvements, personal identities, and level of outness. For example, research suggests that trans students generally have more positive experiences in smaller classes, as well as in courses and majors in the social sciences, arts, humanities, and education, rather than in courses and majors in science, technology, engineering, and math (STEM) fields. Trans students benefit as well when they receive support from faculty members in and outside of the classroom, when they connect with other trans students, and when they form romantic and social relationships with supportive peers.

Differences by Gender Identity

One of the main factors in how trans students experience college is their gender identity, with trans women and nonbinary trans individuals more likely than trans men and gender-nonconforming individuals to report instances of harassment and discrimination. For example, nonbinary trans students are more likely to be misgendered than binary trans students, as others fail to ask them how they identify and typically categorize them as female or male. Moreover, because their gender expression may not be stereotypically masculine or feminine, nonbinary trans students also report being more concerned than binary trans students about their safety on campus, and some decide to present themselves in more masculine or more feminine ways than they desire in order to lessen the risk of harassment.

At the same time, trans female students more often experience mistreatment in relation to gendered campus facilities. In analyzing data from the National Transgender Discrimination Survey (2011), social work scholar Kristie Seelman found that, compared with the gender-nonconforming participants who had attended college, the trans female participants were more than three times as likely to have been denied access to gender-appropriate campus housing and nearly three times as likely to have been denied access to campus restrooms. Because of the pervasiveness and severity of harassment and discrimination, trans women are more likely than members of other trans groups to drop out of college. Seelman suggests that the targeting of trans women relates to how they are often not seen by the larger society as "real" women and how "women-only" spaces are policed to exclude trans women. These experiences reflect what writer Julia Serano called "transmisogyny," the ways in which the hatred toward trans people and hatred toward women intersect in the oppression of trans women.

Differences by Race and Other Minoritized Identities

Similarly, the intersecting of racism and bias against trans people results in trans students of color experiencing campus discrimination more frequently and more harshly. Seelman found that trans people of color were nearly 1.4 times as likely as white trans people to be denied access to gendered college facilities because of their gender identity. Trans people of color, particularly American Indian, Latinx, African American, and multiracial individuals, are also more likely than white trans people to report having left college as a result of repeatedly encountering harassment and discrimination.

Little research has examined the experiences of trans students with other minoritized identities. A notable exception is a 2018 study by Ryan Miller and Sandra Dika on the experiences of more than 400 LGBTQ+ students with a psychological disability (e.g., anxiety, depression, posttraumatic stress disorder) at a southern research university. They found that less than 20% of the trans students indicated that they felt that their gender was respected on campus, compared with 85% of the cis male students, and nearly one third of the cis female students and less than 40% of the trans students felt a sense of belonging, compared with close to half of the cis students.

Differences by Level of Outness

Another factor that has a significant role in the college experiences of trans students is their level

of outness. If someone is not known as trans, they are unlikely to encounter harassment and discrimination based on their gender identity, and conversely, the more someone is thought or known to be trans, the more visible they become and the more likely they are to encounter anti-trans bias. For this reason, out trans students often view the climate on their campuses more negatively than students who are more closeted. Education researchers Jason Garvey and Susan Rankin found that trans students who indicated being more out about their gender identities also had more negative perceptions of the inclusivity of the curriculum, the classroom climate, and the overall campus climate than those who were less out.

Similarly, a 2019 national study of more than 500 trans undergraduate and graduate students by Abbie Goldberg, Genny Beemyn, and JuliAnna Smith found that the greater the participants were involved in campus activities, the more negatively they perceived the climate on their campuses. Given that trans students are among the most marginalized college groups, it could be that greater campus engagement more frequently exposes individuals from these groups to staff, faculty, and other students who are hostile to their identities, which leads them to view their institutions as more hostile. While this finding makes intuitive sense, it runs counter to decades of research on students in general, which shows that students who are more involved at college, including having more frequent interactions with faculty, socializing more with a diversity of people, and spending more time working with other students, express greater overall satisfaction with their college and a greater willingness to reenroll.

Given that out trans students more commonly experience harassment and discrimination, it is also not surprising that those who report feeling more at risk for mistreatment are more likely to try to avoid the disclosure of their gender identity. Obviously, not all trans students can or want to be closeted. If they are medically transitioning or identify and present as gender nonconforming, most students will be readily seen as trans. But other trans students, who can and want to keep others from knowing their gender identity, often do so in order to lessen the risk of negative consequences. For example, nearly half of the respondents in the 2015 U.S. Transgender Survey who indicated having attended college stated that none of their classmates knew that they were trans. Among the participants in the *2010 State of Higher Education for LGBT People*, 65% of the transmasculine students, 55% of the transfeminine students, and 18% of the gender-nonconforming students surveyed stated that they did not disclose their gender identity to avoid harassment and discrimination. The significantly lower percentage for the gender-nonconforming students in the study seemingly reflects the desire of many of these students to be open about their identities in order to avoid being placed within a gender binary, even if this means an increased likelihood of experiencing mistreatment.

How College Experiences Vary by Aspects of the Institution

Along with individual factors like identity differences and level of outness, trans students' college experiences are greatly influenced by both the type of institution and the specific institution they choose to attend. While all colleges remain rooted in a gender binary and none do enough to create a welcoming and inclusive campus environment for trans students, especially nonbinary students, some do much more than others to create a supportive climate. For example, the Campus Pride Trans Policy Clearinghouse lists more than 250 colleges that have a gender-inclusive housing option; a similar number that enable students to use a chosen name, instead of their deadname, on campus records and documents; and about 40 colleges that provide a means for students to indicate the pronouns they use for themselves on course rosters.

An examination of the colleges on these lists shows major differences between the types of institutions that have and do not have trans-inclusive policies. Not surprisingly, institutions with trans-inclusive policies tend to be large state universities and small liberal arts colleges, in urban areas, and in the Northeast, on the West Coast, and in parts of the Midwest. Relatively fewer campuses with trans-inclusive policies are religiously affiliated institutions and community colleges, in rural areas, and in the South, the Great Plains, and Mountain West. Similarly, the study by Goldberg, Beemyn, and Smith found that private, 4-year, nonreligious colleges and universities provided the largest

number of trans-inclusive services and supports, followed by public 4-year colleges and universities. The public and private 2-year colleges included in the survey had the fewest, even fewer than 4-year religiously affiliated institutions.

Community Colleges

Studies involving out trans students at community colleges indicate that they often experience particularly hostile climates and lack access to supportive campus resources. Community colleges can be especially unwelcoming because most are commuter campuses that provide limited services to students in general and do not sponsor any programs specifically for trans students. Campus life at these schools is almost exclusively focused on the classroom, yet most community colleges do little to address the classroom climate for trans students. Community college students surveyed in the *2010 State of Higher Education for LGBT People* felt that faculty members at their institutions were generally indifferent to or unsupportive of trans people and indicated that few lectures and readings were trans inclusive. Overall, many of the students were uncomfortable with the classroom climate and did not feel safe to be seen as trans at their community colleges.

Conservative Religiously Affiliated Institutions

Similar to their peers at community colleges, trans students at institutions affiliated with conservative religious traditions often receive little support, if not outright opposition, from other students and sometimes from faculty and staff members. But because cis students at conservative Christian and Jewish colleges generally hold more negative views of trans people than do their counterparts at secular and more liberal religious colleges, the environment at these institutions may be especially hostile.

The negative climate is fueled by institutional doctrines and codes of conduct that often condemn trans people and gender nonconformity. For example, Ozark Christian College (2019) in Joplin, Missouri, included in its "Community Guidelines" the following statement:

> Consistent with our commitment to God's design for gender identity, the public advocacy for or the act of altering one's birth-gender identity through medical transition or transgender expression is prohibited. This commitment to gender identity also applies to, but is not limited to, the use of bathrooms, locker rooms, student housing, and participating in gender-specific college groups, clubs, and organizations. (p. 3)

Because the Trump administration did not consider trans students to be protected from discrimination under federal law, schools like Ozark Christian College could openly deny them admission or expel them, and several religiously conservative colleges received media attention in the late 2010s for indicating to trans students that they were not welcome at their institutions.

On the positive side, because of the resiliency of trans students, which leads some to come out and push back against the oppression they experience on campus, the climate at a number of conservative religiously affiliated institutions is beginning to improve and will likely continue to do so. The growing acceptance of trans people in the dominant society, especially among members of Gen Z, is also contributing to more favorable campus environments. For example, in response to advocacy from students, staff, and alumni, three Mennonite colleges announced in 2015 that they would start to hire openly LGBTQ+ staff and end their membership in the Council of Christian Colleges and Universities, an association consisting primarily of white evangelical Protestant institutions that opposes employing and enrolling LGBTQ+ people.

Historically Black Colleges and Universities

Some of the religiously affiliated colleges that have sought to improve their climates for trans students in recent years are HBCUs. A majority of HBCUs were founded by churches, and about half of the slightly more than 100 HBCUs that exist today remain religiously affiliated. Being rooted in the Black church and other socially conservative religions, as well as having firmly entrenched race and class expectations about what constitutes the ideal for a "race man" or "race woman," has meant that HBCUs have traditionally been hostile toward trans people.

A prominent example of the historically negative climate for trans students at an HBCU was the decision by Morehouse College, a men's institution, to enact an "Appropriate Attire Policy" in 2009 that included a ban on traditionally women's clothing on campus. Students who repeatedly violated the dress code risked academic suspension. The prohibition received significant support among cis, heterosexual students and alumni but was challenged on campus by gay and gender-nonconforming students, which led to the provision being quietly removed from the policy in 2015.

Many contemporary trans students at HBCUs report having a more positive experience because many of the institutions have become more supportive in response to LGBTQ+ student activism. Prior to the 2010s, few HBCUs had taken even the basic step of adopting LGBTQ+-inclusive nondiscrimination statements, but since then, more than two thirds have added "sexual orientation" and more than one third have added "gender identity" to their policies. Although HBCUs still lag behind many predominantly white institutions in having LGBTQ+ student groups and resource centers, it is noteworthy that many of the leading HBCUs are now seeking to facilitate the inclusion of trans students, rather than ignoring them or trying to keep them marginalized. Reflective of these trans-positive changes, the two HBCUs that are women's colleges—Spelman and Bennett Colleges—have changed their admissions policies to accept applications from trans women, and Morehouse now considers trans male applicants.

Historically Women's Colleges

The inclusion of trans students at women's colleges became a contentious issue in the late 1990s and early 2000s, when trans students began to publicly self-identify in greater numbers at the leading women's colleges, as they did at many other colleges across the country. But the situation was different at women's colleges because the trans men and nonbinary individuals who had been assigned female at birth (AFAB) who came out did so in an environment in which all students were expected to identify as women. The result was that they experienced invisibility, hypervisibility, and oppression from administrators, faculty, and other students. They were frequently misgendered if people did not know or respect that they identified as trans and often had their right to be on campus questioned if they were known or thought to be trans. Transmasculine and nonbinary AFAB students at religiously affiliated and more conservative women's colleges have often had even more negative experiences, with students being expected to adhere to traditional feminine norms in their appearance.

Since the mid-2000s, support for trans men and nonbinary AFAB students has grown among their cis peers at women's colleges—at least at some of the more prominent, nonreligiously affiliated institutions—as more transmasculine and nonbinary individuals have come out and advocated for change. Because of this increasing visibility, many women's colleges have been forced to consider how having non-female-identified students aligns with their institutions' missions and values. As of 2020, 17 women's colleges, including such leading institutions as Barnard, Bryn Mawr, Mills, Mount Holyoke, Smith, Spelman, and Wellesley, had published policies that enable individuals assigned female at birth who begin to identify as trans men after matriculating to continue to earn a degree. Thirteen women's colleges have also explicitly stated that they consider nonbinary AFAB individuals for admission, but only Mount Holyoke, Simmons, and Agnes Scott unambiguously accept applications from openly trans men.

As controversial as the presence of trans men and nonbinary AFAB individuals at women's colleges has been at times, the inability of trans women to be considered for admission if their legal sex was still male became an even bigger concern. The issue gained national attention in 2013, when Smith College declined to consider a trans woman's application because her financial aid form indicated that she was male. In the wake of the rejection, students at Smith organized to change the college's admissions process, and other women's colleges began to adopt trans-inclusive policies without the need for students to protest. In 2014, Mills, Mount Holyoke, Simmons, and Scripps announced that they were expanding their admissions policies to consider any student who self-identifies as a woman and were joined by Bryn Mawr, Wellesley, Smith, and

Barnard the following year. As of 2020, 19 women's colleges have published policies indicating that they accept applications from trans women without requiring them to have transitioned or to have all of their legal documents reflect their gender identity. At least another five women's colleges reportedly do the same but do not provide this information publicly.

Given that trans women are women, denying them the chance to apply to women's colleges sends the message that their identities are fake and not to be believed. Thus, the institutions that have changed their policies are demonstrating their acceptance and support of trans women in a significant, tangible way. But, for some of these colleges, considering trans women for admittance seems to be the extent of the support they currently provide. They do not have a chosen name option for nonlegal campus records and documents, cover hormones and gender-affirming surgeries under student health insurance, or offer academic and personal assistance tailored to the needs of trans people. Hopefully, as more trans women attend women's colleges, the institutions will implement additional trans-supportive policies and practices.

Other Types of Institutions

Although 4-year public universities and private nonreligious and more liberal religious colleges may not present unique challenges to trans students, these types of institutions still have histories of trans exclusion and often negative campus environments. Research shows that trans students at such institutions indicate having higher levels of alcohol abuse, anxiety, depression, suicidal ideation and behavior, and other mental health issues than do their cis peers because of discrimination and harassment and, as a result, encounter greater obstacles to their social and academic well-being. For example, a meta-analysis of seven national college surveys from 2015 to 2017, which involved more than 900 institutions, found that the trans participants were three times more likely than their cis counterparts to report self-injury and having seriously considered suicide and two times more likely to report being so depressed that it was difficult for them to function in the previous 12 months.

Campus Microclimates

Along with ignoring differences between types of colleges, research on trans students generally fails to consider differences within individual college environments, treating a campus as a single entity. But trans students have often had more negative experiences in some college settings than others; in particular, they report a greater extent of discrimination and harassment and less support in athletics, fraternities and sororities, and residence halls than in other campus microclimates.

Athletics

Few studies have examined the experiences of trans student athletes, presumably because only a handful have been public about their trans identities while they were competing. Notable out trans male athletes have included Kye Allums and Keelin Godsey, who played on women's teams before medically transitioning (basketball at George Washington University and the hammer throw and other field events at Bates College, respectively), and Schuyler Bailar and Taylor Edelmann, who switched from women's to men's teams after they began identifying as trans men and taking testosterone (swimming at Harvard University and volleyball at Purchase College, respectively).

From media accounts, it seems that, of the four, Bailar and Edelmann had the most positive experiences as out trans athletes. They described their institutions' athletic administrators and coaches as supportive and felt embraced by both their former female teammates and their new male teammates. They also did not receive negative reactions in the media and from members of other teams. The fact that Bailar and Edelmann were playing on men's teams and were not leading the athletes on their teams undoubtedly contributed to their largely favorable reception. By seeking to become a part of the dominant gender group, they reinforced patriarchal values but, at the same time, were not seen as intimidating or emasculating because they were less successful in competing against other men.

In sharp contrast, Godsey, the first widely known trans college athlete, encountered a tremendous amount of hostility, seemingly because he remained on the women's team and was extremely successful, including being a 16-time All-American and holding the Division III record in the women's

hammer throw. Critics repeatedly accused him of cheating by taking testosterone, even though Godsey had announced that he was not planning to medically transition until ending his athletic career and, as evidence, regularly passed drug screenings. Characterizing his college athletic experience after graduating in 2006, Godsey indicated that he found it nearly impossible to be trans and an athlete, even though both were central parts of his identity.

Trans female college athletes have encountered even harsher opposition to their right to participate on women's teams than nonmedically transitioning trans men, because of the common misperception that they have an unfair competitive advantage due to being assigned male at birth or, worse, that they are actually still men. The National Collegiate Athletic Association (NCAA) requires trans women to complete 1 year of hormone therapy before playing on a women's team in order to address any possible physical edge, but even after they do so, they are not necessarily accepted as women. The first publicly out trans woman in women's college sports, Gabrielle Ludwig, a basketball player for a California community college in 2012 and 2013, received negative media coverage and regularly encountered anti-trans harassment from the fans of rival colleges. She was embraced by her coach and teammates, but that may not always be the case for trans female athletes when roster spots, playing time, and unwanted public attention are at issue or when they have not had bottom surgery, as Ludwig had done.

More recently, two college runners have come out publicly as trans women. Competing for Franklin Pierce University, CeCé Telfer won the 2019 Division II National Championship in the 400-meter hurdles, becoming the first out trans woman to win an NCAA title, and June Eastwood, a cross-country runner at the University of Montana, became the first out trans woman known to have competed on a NCAA Division I women's team in 2019. Both were strongly attacked by conservative media outlets for being "really men" who were racing against women because they could not be as successful on men's teams. Until the climate for trans female athletes significantly improves, few trans women will feel comfortable being out while they compete, and many will forgo competing altogether to avoid the possibility of disclosure and subsequent harassment.

Fraternities and Sororities

With the other two historically single-sex environments—women's colleges and collegiate athletics—taking significant steps in recent years to incorporate trans people, fraternities and sororities are the last major bastion of trans exclusion on college campuses. Not until the mid-2010s did some non-LGBTQ+-specific national fraternities and sororities issue formal policies enabling trans students to be eligible for membership. The first fraternity to admit trans men was Sigma Phi Epsilon in 2015; the first sorority to admit trans women was Alpha Chi Omega in 2017. Only a few other national fraternities and sororities have since followed suit. All have policies that allow any individual who identifies as either a man or woman to be considered for membership, but some require legal documentation that proves the person's gender identity, which is a difficult if not impossible hurdle for many traditionally college-aged trans men and women. Moreover, some of these policies are silent on whether a fraternity member who transitions to female or a sorority member who transitions to male can remain in the chapter, and none address the inclusion of nonbinary trans students.

With fraternities and sororities just beginning to accept openly trans women and men for membership, little has been written about their experiences. The students who are out as trans will presumably have a mostly positive experience because chapters will not be accepting them for membership if they are unsupportive. Less clear is the climate for trans students who come out after becoming members, especially for those who identify as a gender different from the sex designation of the chapter and begin to transition. And even more uncertain is the extent to which fraternities and sororities may continue to covertly discriminate against trans students by denying them membership based on their gender identity. Hopefully, as campuses in general become more supportive of trans students, so too will fraternities and sororities, as has been the case with cis LGBQ+ students.

Residence Halls

Living in a residence hall can add to the challenges that trans students face at college, because if other residents are hostile toward trans people, it can be difficult to avoid them; they literally know where you live. Trans women and men who are not out in their residence hall are often placed in an even more difficult situation by having to hide aspects of their bodies from roommates and other residents if they have not medically transitioned. For students in this predicament, their residence hall—their home at the institution—is far from a safe place.

It is understandable that trans students would not want to be out for fear of encountering harassment and discrimination or being treated differently, such as a trans man no longer being respected as male if he discloses that he was assigned female at birth. Unfortunately, most colleges exacerbate these fears and the likelihood of mistreatment for those who are out by failing to develop a means for incoming trans students to find other trans or trans-supportive roommates and by basing housing on sex assigned at birth rather than gender identity, so that many trans women and men are forced to live with roommates whose gender is antithetical to how they see themselves and nonbinary students are unlikely to be matched with another nonbinary person. Trans students also often have to contend with gendered bathrooms in residence halls and a lack of support from hall staff to be able to use the facility that best reflects their gender identity.

The extent to which trans students often face institutional and individual discrimination in residence halls is shown by a 2016 study conducted by Jonathan Pryor, David Ta, and Jeni Hart. Interviewing a dozen trans students from 11 different colleges, they found that most of the participants were either assigned a roommate of the "wrong" gender who was unsupportive of them as a trans person, which led them to feel unsafe, or forced to be housed away from their friends in a single room because of the lack of a trans-supportive housing option, which led them to feel lonely and marginalized. The absence of gender-inclusive bathroom facilities in their residence halls was also a tremendous problem for some of the students, who feared harassment or violence if their hall mates discovered that they were trans. One interviewee got up at 6 a.m. just to shower without being seen by other residents and then often went back to sleep before she awoke for classes. As a result of these experiences, almost all of the participants sought support and a sense of community away from their residence halls, and only a few developed significant relationships with the people with whom they lived.

Trans student activism in the 2000s led colleges to begin providing gender-inclusive housing, in which students are assigned roommates regardless of gender, starting with Wesleyan University in 2003. As of 2020, more than 270 institutions have established this type of housing option, with most limiting it to specific floors, buildings, or parts of campus. Some programs are targeted to LGBTQ+ students, whereas others are open to any student wanting to live with someone of a gender different from themselves. But gender-inclusive housing does not address the underlying problem—that most campus housing continues to normalize a gender binary and remains closed to trans students. Thus, although gender-inclusive housing is an important reform to traditional housing options, advocates argue that colleges need to do more. To be truly supportive of trans students, institutions must change their housing process to have all students indicate their gender identity and then use this information, rather than assigned sex, for residence hall placements. Such a system enables trans women and trans men to be treated as women and men, respectively, and gives nonbinary trans students the ability to live with other nonbinary people. At the same time, colleges should allow all students to have roommates of any gender, as there is no legitimate reason why students should not have the choice to live wherever they want with whomever they want on campus, just as they can do if they live off-campus.

Other Microclimates

While athletics, fraternities and sororities, and residence halls may be the three most hostile microclimates at times for trans students, they are by no means the only aspects of campus life in which trans students can feel marginalized or excluded. Other microclimates, including classrooms, campus workplaces, college offices and

centers, student activities, and student organizations, can also be discriminatory environments. Thus, trans students cannot be assured of having a positive experience in any campus setting, which is a stark indicator of the need for colleges to be doing much more to create trans-inclusive climates.

Coming Out

Coming out is the process by which individuals acknowledge their own sexual or gender identity to themselves (i.e., coming out to oneself) and then share this identity with others (coming out to others). Although typically thought of as a one-time event, coming out for trans people is a

developmental and lifelong process shaped by multiple aspects of an individual's life.

Coming Out as a Developmental Process

Generally, the first step of coming out for trans individuals involves a period of self-awareness. This process can begin very early for some trans people. Around the age of 2 to 3 years old, the majority of children develop the ability to label gender and are thus able to verbalize differences between boys and girls (conferred to them by societal conceptualization of male and female genders). Highly verbal children at this age may also begin to self-label as boys, girls, or another gender. Some children even use gender-creative names to describe themselves at this time (e.g., "I'm a boygirl" or "I'm a girlboy"). Gender stability, or the sense that one's own gender and the gender of others remains stable across time, develops around the age of 3 and a half to 4 and a half years of age. This task involves the understanding that one will grow up along the same gender trajectory (e.g., a girl will grow up to be a woman). Gender constancy develops a few years later around the age of 6 and describes the phenomenon by which children begin to understand that external features do not change someone's gender (e.g., a male child wearing a dress is still a male child). At this age, some trans children may begin to experience anxiety when they understand that their physical body is unlikely to change as they once might have imagined. At any point in the process described above, trans children may become aware of a difference between how others perceive and label their gender and how they understand their own gender.

Children as young as 3 thus may begin the coming-out process by sharing their gender identity verbally. Coming out for younger trans children may also include social transition. Children with affirming families and in safe environments may begin to present in their affirmed gender, which will involve a coming-out process as community members relearn the child's gender identity. Other families feel safer embarking on a social transition for their child in a new setting where the child's sex assigned at birth remains unknown to others in the community.

There are many trans children who recognize that they are different in some way but for a variety of reasons do not feel comfortable sharing this; those who do share their true gender identity with caregivers are often ignored or, worse, chastised and punished. For such children, the development of a "false gender self" may emerge, whereby the child begins to repress aspects of their known gender identity and instead attempt to fit into the gender role imposed on them by others. Unsurprisingly, this situation often leads to significant mental health sequelae for the child. Such children may not attempt to come out until later in development and even into adulthood.

The awareness of gender identity may also begin to consolidate during pubertal development. Many trans individuals do not become aware of their gender until physical changes lead to anatomical discomfort. For example, changes in breast development and the onset of menses can elicit significant discomfort and increased awareness or consolidation of gender identity in transmasculine individuals. For adolescents, the coming-out process may be complicated by several other developmental tasks. For example, adolescents are beginning to develop a sense of who they are and the kind of person they want to become. The psychosocial developmental task of adolescence is to begin differentiation from one's family and gain acceptance from one's peer group. Thus, dealing with feelings of gender dysphoria might feel especially overwhelming in the context of increased pressure to conform and solidify one's sense of self. Yet many trans adolescents do come out around this time and often confide first in their peers, teachers, or online community.

After adolescence, many trans young adults begin to feel increased self-acceptance and ability to come out as they continue the process of individuation from their parents and gain agency around self-identification and decision making. Indeed, recent increases in societal acceptance of gender diversity have allowed trans adolescents and young adults to feel more comfortable coming out in their communities and to their families. For example, many trans people cite the importance of visible trans people in the media, such as Laverne Cox or Chaz Bono, as positively influencing their own ability to come out. On the other hand, some trans adults do not develop the confidence to come out until a "trigger event." Many older trans individuals describe a significant event such as the

death of a loved one, diagnosis of a medical condition, or their children moving out as the impetus for coming out and finally beginning to live in their authentic gender identity.

The initial process of self-awareness and coming out is often followed by a period of exploration. Exploration may include connecting with other trans individuals and joining the trans community through various activities online and/or in person. Experimentation with gender identity and presentation also occurs at this stage. Adolescents and adults may begin to explore new forms of dating relationships or sexual intimacy in their affirmed gender role. The process of finding comfort in intimacy as a trans person may take time, especially if one undertakes gender-affirming interventions to change one's physical body. The development of intimate partners who one can trust and can communicate with openly is thus especially important during this phase. A "final" stage of the coming-out process may involve integration of one's trans identity with other aspects of identity, such as racial, ethnic, and/or religious identity. In this stage, the individual has developed pride and a strong sense of their gender and sexual identity, and these aspects are consolidated into who they are as a whole person. Trans individuals at this stage may be less concerned with labels or with "passing" (i.e., being perceived as cisgender) and instead experience deep self-acceptance of their own unique gender journey.

The coming-out process may vary vastly for different trans people. The stages above provide a model for understanding the common tasks many individuals experience in their coming-out process; however, in reality, individuals typically do not move through these stages in a stepwise fashion and instead move fluidly across stages and even revisit stages at later points in their life. Indeed, the assumption that all individuals reach a "final" stage should be cautioned against, given that the process of coming out for trans individuals may be renegotiated at various times throughout one's life. It is also important to consider that many Western models of coming out, such as the one described above, are based on stage theories of bereavement (e.g., grieving associated with death of a loved one). Thus, these models may be less relevant in cultures with revered or well-established roles for gender and sexual minorities (e.g., some indigenous or native cultures).

Coming Out in Context

The coming-out experience is shaped by interactions between psychological factors and the individual's social environment. Several individual and environmental factors influence the coming-out process, particularly the way in which trans individuals work through the process of coming out to others.

Family of Origin

Coming out to one's family members and parents can cause anxiety and may be risky if an individual is financially dependent on others. A trans person may face abandonment by the family, loss of financial support, or eviction from the family home. To avoid this, some trans individuals may avoid coming out and instead conform to their family members' gender expectations. Conforming to avoid negative repercussions of coming out to family members may contribute to mental health sequelae as the individual begins to feel disconnected from themselves and isolated from others. In some cases, family members may have an unfavorable reaction initially; however, many trans individuals find that they are later able to reestablish, and even strengthen, relationships with their family members.

Coming out is thought of as a personal experience, but it also affects family members regardless of the trans person's age. Family members of trans people experience their own process of coming out at work, to friends, and to other family members. Parents often report experiences of grieving the gender role they assumed their child would take in the future. In some cases, siblings can be strong allies during the coming-out process; in fact, research indicates that sibling support for trans youth can buffer negative reactions from other family members.

Trans people who come out in adulthood may already have their own family, including a spouse and/or children. Having a spouse or parent who comes out as trans requires an adjustment on the part of the family. These family members must find ways to negotiate coming out for themselves as a

family member of a trans person. Children may have trouble adapting to having a parent who is different from their peers' parents, particularly during adolescence, when conformity tends to be highly valued. Thus, support for the trans person's spouse or children is often beneficial during the coming-out process.

Relationships and Dating

Coming out in the context of intimate relationships or in a dating context can be a difficult experience for many trans individuals and varies depending on the nature of the intimate relationship. Coming out in the context of a casual dating relationship is distinct from coming out to one's intimate partner or spouse of several years. When a partner comes out as trans, it may affect the sexual identity of both people in the relationship. In dating and intimate relationship contexts, trans individuals often need to consider their own safety in coming out. Some trans individuals have reported significant sexual and domestic violence when coming out to a partner. Partners might feel angry, confused, or betrayed by the disclosure, which can precipitate physical, emotional, or financial abuse. Of course, many partners are immensely supportive and become strong allies for their partner and the trans community.

Coming Out Outside the Home: School and Work

Coming out at school or work can take significant preparation for many trans individuals and is highly dependent on culture of the school or work environment. During middle school or high school, the strong desire to "fit in" typical of adolescence may lead to attempts to conform to gender role expectations, rather than coming out. However, attending college in a new environment away from parents, family members, and friends can allow trans individuals to "start over" and experiment with gender expression in a new, possibly more accepting, environment. The school context is important with respect to the coming-out experience, and unfortunately, schools can vary drastically in their levels of acceptance and support for trans students. The presence of a lesbian, gay, bisexual, transgender, queer, intersex, and asexual (LGBTQIA+) student organization; availability of gender-inclusive bathrooms; and use of students' chosen name and pronouns in the learning environment are all factors that can help to promote a safe and accepting environment for trans individuals.

Disclosing one's gender identity to coworkers and employers may be highly stressful since there are no federal laws protecting trans individuals from being terminated due to their gender identity. Thus, trans individuals may be faced with the choice of risking their career and financial stability or hiding their gender identity at work. Understandably, this dilemma often leads to avoidance of coming out. Some trans individuals solve this problem creatively by choosing to work in fields that typically employ members of the gender with which they identify. For example, a transmasculine person may seek work as a limousine driver, since the uniform for this job is typically a suit. This would allow them to express their gender identity by wearing traditionally masculine clothing without facing criticism for their gender presentation. Other trans individuals might seek out workplaces that are more likely to be accepting of gender diversity such as social service organizations that serve LGBTQIA+ people.

The Importance of Geographic Location

The geographic location of the individual is important since the level of acceptance of gender minorities differs by city and region. Coming out in a rural area or conservative city may be drastically different from coming out in an urban area or progressive city, especially with respect to potential violence. This is especially important for trans women of color, since Black trans women continue to be the target of the majority of severe anti-transgender violence, including homicide. Trans individuals may report the need to be highly aware of potential threats in unfamiliar surroundings. For example, a trans person may seek to use only gas stations with credit card payment capabilities in order to minimize interactions with local people in areas they perceive as unaccepting of trans people.

On the other hand, trans individuals in rural areas or conservative cities who have strong support systems are often able to manage the stressors of coming out in these communities positively.

Factors that influence the safety of a particular geographical location with respect to coming out and being seen as trans include community awareness and acceptance of gender minorities, the size of the trans community (including well-organized and accessible trans resources), knowledgeable health care providers, and the passage of laws protecting against gender-based discrimination.

Methods of Coming Out

Typically, the first disclosure is reported to be the most difficult; however, the results of this disclosure can often increase one's confidence in coming out to others. Many trans individuals first come out to people they feel most secure with (e.g., their best friends), leaving those whom they feel less secure with (e.g., their employer) until last. Many trans individuals now first come out online (e.g., under an alias to an online friend that one has not met and may be unlikely to meet in person) as a way to experiment before coming out to people they know in person. If these experiences go positively, they may begin to come out to more people and/or change their name, pronouns, or gender identity on their online profiles. Along with the Internet, mobile devices have allowed individuals to come out via text, which may be easier since text messaging does not necessitate a face-to-face interaction. Others might use an implicit form of coming out, for example, by adopting a new hairstyle or clothing as a way to indicate a change in their gender identity.

Benefits and Barriers to Coming Out

Trans people can experience enormous benefit but also substantial stress and threats to health and wellness from coming out. This section discusses some of the benefits and barriers to coming out that trans people may face.

Benefits to coming out include the opportunity for trans people to live authentically and express their gender in a way that matches their gender identity. Trans people may feel psychologically more free and able to connect meaningfully with others in their lives when they are living as their "true selves," so interpersonal relationships may improve. Coming out may allow trans people to find a community of supportive trans peers and others who accept them for who they are. They may take steps to change their physical appearance to align with their gender identity or to use a different name and pronouns. Coming out may also be a step toward pursuing gender-affirming medical or surgical interventions if they so desire, although not all trans people want these interventions.

Benefits to coming out include a reduction in risks associated with concealing one's gender identity. Stress from feeling the need to conceal an essential part of oneself, such as one's gender identity, is known to have detrimental mental health consequences. Some trans people experience substantial stress and isolation from concealing their gender identity. Reasons trans people may conceal their identity are various and can include fear of rejection by family and friends, loss of employment, or discrimination. These feelings can contribute to anxiety, depression, nonsuicidal self-injury, or suicidal thoughts or actions. Coming out may improve a trans person's mental health if it lifts the burden of concealing an essential part of themselves and allows them to live as their authentic selves.

On the other hand, coming out in an environment that is not supportive can expose trans people to multiple serious risks. These risks include abuse, harassment, discrimination, severe violence, loss of employment and housing, and isolation from family and peers. Youth in particular are vulnerable to family rejection since they usually are still living at home and are dependent on parents or guardians. This leads to higher rates of homelessness among trans youth compared with their cisgender peers.

After coming out, trans people may be called upon to explain their gender identity to family, friends, or peers. People close to the trans person may be well intentioned in trying to understand their experience, but repeatedly explaining one's gender identity can be experienced as burdensome and exhausting to some trans people. Lack of affirmation may occur if others refuse to accept or believe a trans person about their identity. Nonbinary identified people may be more vulnerable since their gender identities are less well understood and accepted in Western cultures. Therefore, in addition to lack of affirmation of their gender identity, nonbinary people may also face rejection from those who do not believe their gender identity is valid or real.

Many factors play a role in the societal level of acceptance of trans people. For example, many religions are not accepting of trans people, so communities that hold strong conservative religious beliefs may be less likely to accept and affirm trans after coming out. On the other hand, some trans people report their religious or faith community has welcomed them as a trans person and is a source of support and strength for them. Some trans individuals report that their faith or religious beliefs helped them to persevere through difficult times to finally be comfortable with who they are. In some cases, they were able to use their religious or spiritual beliefs as guiding principles and incorporate religion into their gender identity development to help facilitate rather than impede the process. The same may be true in certain cultural contexts or racial/ethnic communities since different cultures have diverse views about trans people. For example, in traditional Hawaiian native culture, *māhū* is a term used to describe someone who embodies male and female spirits and would be considered trans in Western cultures. Māhū have an important spiritual and cultural function in Hawaiian culture so trans people living in this setting may have a different experience from trans people living in Western cultures.

Another benefit of coming out for trans people may be an increased sense of belonging to the LGBTQIA+ community. However, although sexual minorities (i.e., lesbian, gay, bisexual, etc.) and gender minorities are often thought of as one community, they may have distinctly different experiences. In fact, trans individuals have reported discrimination from within the LGBTQIA+ community, so it cannot be assumed that increased contact with LGBTQIA+ peers will necessarily benefit trans people. Trans people of color have reported particularly high rates of exclusion and discrimination from within the LGBTQIA+ community.

Regardless of the context of coming out, all trans people need support in this process. Ideally, support should come from various sources depending on the needs and desires of the individual. Family, friends, and intimate partners can support the trans person on a personal level. Schools can support trans students by providing education about gender diversity to students, teachers, and staff. Workplaces can support trans employees by implementing trainings around gender diversity and respect for trans people. Schools and workplaces can institute strong antibullying and antidiscrimination policies and have in place a mission statement that includes protection on the basis of gender identity and gender expression. Psychological support can be very helpful as trans people navigate the coming-out process. This may include individual psychotherapy, group therapy, or community-based support groups. In remote settings or rural areas where there may not be many trans people, support groups or mental health services may be accessed online. Trans people who want to pursue gender-affirming medical or surgical interventions can be supported by their primary care provider or a specialist (e.g., endocrinologist) for gender-affirming hormone treatment and by surgeons experienced in working with trans people for gender-affirming surgical procedures.

The coming-out process for each trans individual is highly unique. Some common experiences in the coming-out process are detailed here; however, it is important to note that each person experiences their own journey in exploring and understanding their gender and sharing this identity with others. As noted earlier, several contextual factors influence how comfortable and safe trans people feel when coming out. These factors include geographical location, nature of close relationships, federal and state policies, and one's support system, to name a few. Support for trans people who are coming out can come from various sources, including family members, friends (online and offline), peers, colleagues, professional LGBTQIA+ organizations, the trans community, one's faith community, and health care providers. It is crucial that trans individuals be supported wherever they are in the coming-out process to optimize long-term mental health and psychosocial adjustment.

Communication

While the communication field rarely addressed trans lives or experiences during the 20th century, trans studies began to emerge as a scholarly topic area during the first two decades of the 21st century. Research in various subdisciplines has addressed many nuanced aspects of trans experience with respect to verbal and nonverbal communication practices.

In its broadest sense, communication is the continual, interactive exchange of symbolic meanings. Words, gestures, and facial expressions are obvious symbols, but most human action can be symbolic in that others are influenced by it and provide various forms of feedback in response, both consciously and unconsciously. The topic of communication is quite broad, given that communication takes place within virtually all aspects of life. This means that scholars in most academic fields are studying communication to some degree. Theory specific to the communication discipline, however, has been developed and expanded since the early 20th century. This entry addresses the trans-related academic work of communication scholars in communication journals and texts, although it should be noted that the general topic of communication is sufficiently broad to allow for similar work to be done within other academic fields as well. Beginning with an outline of the study of human communication generally, the entry continues with a detailed description and explanation of the ways in which communications scholarship and its various subdisciplines are exploring the foundations of gender identity and societal expectations regarding expression of gender. Next, the entry presents an extended discussion that focuses on an array of issues relating to trans lives and experiences.

The Study of Human Communication

Human communication has been studied from empirical, interpretive, and critical perspectives using quantitative, qualitative, and rhetorical research methods. Communication scholars tend to work primarily within one research paradigm, and while some might adhere to one research method, others might use different methods for different projects.

While communication scholars have analyzed all forms of communication, the vast majority of this work has not considered the challenges faced or the strategies undertaken by trans people. As a result, those communication scholars who address trans subject matter will routinely cite work from other disciplines—primarily gender studies, sociology, and psychology—and many also publish their work in books and journals outside the communication field. Trans communication scholarship is therefore highly interdisciplinary, not only in terms of the humanities and social sciences but also including the fields of biology and medicine when physical transition practices, such as hormone treatments and surgeries, are discussed.

Types of Communication

For many, the concept of communication tends to be, predominantly, a verbal one—live conversation, phone calls, handwritten documents, print publications, and numerous computer-mediated methods that range from plain text to live video—but most people also realize that nonverbal elements, such as facial expression and gesture, play a role when the speaker can be seen. Both verbal and nonverbal communication are significant during all interpersonal encounters, but for trans individuals, the nonverbal aspects of communication are particularly salient. This section will elaborate on some of the verbal and nonverbal aspects of communication, suggesting how they might be relevant to the study of trans lives.

Verbal Communication

Verbal communication refers to the actual words used—that is, what is known as the lexical component of speech and, for the most part, one's word choice is not read as gendered. In the Western English-speaking world, we might not hear many heterosexual cisgender men using the word *cute* or *adorable* very often, but such word choice differences are insignificant compared to other aspects of verbal speech that have been found to occur more often in the speech of those identifying as one binary gender rather than the other. One example of this is a collection of verbal practices known as tentative speech, which, research has found, occurs more often in the speech of women. This includes qualifying statements such as, "I'm no expert on this, but . . ." (which undermines the statement to come), as well as tag questions such as, ". . . don't you think?" (which requests validation for one's previous statement). Tentativeness also includes verbal hedges that soften one's declarative statements, such as "maybe" and "sort of." Because many trans people take these kinds of details into account in their daily lives, particularly those who wish to be perceived within the binary as men or women, some trans women might make an effort to sound less assertive, while some trans men may attempt to avoid sounding tentative. Such deliberate efforts reflect a desire to unlearn the verbal practices they were raised to enact and that often become habitual and unconscious. Those who identify outside the gender binary, who are not attempting to be perceived as men or women, are less likely to be concerned with these types of details.

One's choice of conversational topic, another aspect of verbal communication, can also reflect gendered expectations and stereotypes, but the overt discussion of one's gender identity is a subject most cis people never feel compelled to address. Many trans individuals put a great deal of thought into their preparation for these "coming-out" conversations, considering how family members, friends, and coworkers might react and what negative repercussions might result. Communication scholars have examined not only the process of coming out as trans but also the ways in which family members interpret the trans identities of their relatives, sometimes perceiving transitioned family members as completely different people from those they used to know.

Another significant aspect of verbal communication for trans people concerns the personal pronouns that individuals use for themselves. Trans people must determine when and how to request particular pronoun use from family, friends, and

coworkers, but then they must also decide how to react when these chosen pronouns are not used. This would include unintentional instances of misgendering (such as when others say that they "forgot" to use the requested language), as well as deliberate refusals to use the chosen pronouns. For those transitioning individuals who achieve an outward appearance perceived as clearly "man" or "woman" by strangers, the need to clarify their pronoun choices might dissipate. However, for those who identify as nonbinary, the need to request particular pronoun use from others may become an ongoing communication chore throughout their lives as they continue to meet new people who are unsure how to address them based on appearance alone.

Nonverbal Communication

Research has found that nonverbal messages from a visible speaker may actually convey more meaning than the words being used. In addition, the nonverbal covers a lot more ground than simply facial expression and gesture. Since verbal communication only refers to the words themselves, the nonverbal includes everything else that conveys meaning. Even the font one chooses for an email or the type of paper on which a letter is written can have an impact on how one's message is perceived.

Paralanguage/Vocalics

Paralanguage, or *vocalics,* refers to nonverbal aspects of speech, such as the volume or pitch of one's voice, as well as the nonverbal sounds one makes (e.g., laughing, sobbing, sighing), to communicate both meaning and emotion. The study of paralanguage began in the mid-20th century, and research findings vary by culture. In the West, communication research has found gender differences in paralanguage. For example, what is known as "uptalk"—raising the pitch of one's voice at the end of a statement to make it sound like a question—is more common to women than to men. Another gender difference concerns the degree to which one responds to the communication of others. Research has found that women are more likely to engage in what is known as the backchannel—responding with facial expressions, sounds, and sometimes actual words without interrupting the other person's speech. These behaviors, such as nodding, smiling, making nonverbal sounds like "uh-huh" or "mm-hm," and speaking brief words like "yeah" or "that's interesting," make a connection with the speaker and serve as acknowledgments that the speaker is being heard. Research has suggested that women are often raised to display more concern for others in these ways, whereas men are often raised to express individualism and competitiveness. A trans person who had been raised to enact gender norms in accord with the sex designated at birth might later choose to revise these acculturated behaviors based on how this person wishes to be perceived. While the pitch of one's voice is biological, in that testosterone thickens the vocal cords, thereby producing a lower pitch, many trans people make careful choices about their manner of speech, with some hiring professional vocal coaches.

Corporeal/Body Rhetoric

The nonverbal meanings conveyed by one's body, in terms of both appearance and behavior, as well as one's presence or absence in a particular space at a particular time, have been described as corporeal rhetoric or body rhetoric. The word *rhetoric,* within the communication field, refers to persuasion. Some scholars restrict this to conscious, intentional persuasion, while others assume a broad definition, including unconscious influence on others as a form of persuasion.

One form of influence that can be conscious or unconscious is what the appearance and behavior of one's body communicates when no words are being spoken. How one looks, as well as how one carries oneself, is often called self-presentation (known within the sociology field as impression management). This is relevant to everyone but particularly important for trans individuals because it includes how one expresses one's gender to others. Thus, how one dresses, whether or not one wears jewelry (and, if so, what type of jewelry), how one styles one's hair, whether or not one wears makeup or tattoos (and in what forms), and what types of objects one carries (e.g., purses, briefcases) are all forms of self-presentation or nonverbal communication.

One also communicates nonverbally through the ways in which one positions or moves one's

body. For example, the degree to which one's hips shift outward when one walks, the manner in which one sits or carries objects, the fluidity or assertiveness of one's gestures or touch, and the frequency of one's smiles are frequently read as gendered by others. Many trans people take these nonverbal details into account in their daily lives, particularly those who wish to be perceived within the binary as men or women. For example, some trans men might deliberately avoid wearing floral patterns or the color pink, while some trans women might make a conscious effort to smile more often than they did before transitioning.

Also nonverbal, as well as nonvocal, is the concept of aural body rhetoric. This refers to the sounds made by the body, particularly when the body cannot be seen by others. Some of these sounds—such as sneezing, coughing, vomiting, or difficulty breathing—are involuntary, but at times they can also be intentionally suppressed or exaggerated. Communication scholars have considered how some trans individuals might attempt to control the bodily sounds associated with restroom use within the stalls of public facilities, given that some of these sounds might suggest particular genital structures, thus creating greater visual scrutiny of these individuals once they leave the privacy of the restroom stall.

Communication Scholarship

When considering communication research that has been done in the past, it is important to note that by far both the scholars and participants in this research have been white individuals, mostly in the United States, and the vast majority likely identified within the gender binary as men and women. The deliberate inclusion of nonbinary gender identities in communication research is very recent and still largely uncommon.

Lists of communication subdisciplines offered by various communication organizations and academic departments may differ. Generally, the field's primary subdisciplines, which often overlap, include interpersonal communication, organizational communication, intercultural communication, rhetoric and public discourse, health communication, mediated or technological communication, and performance studies, which is a research method examining the embodied performance of communication in daily life. This section addresses some of the specific scholarly work being done within the communication field and its subdisciplines on subjects relating to trans lives and experiences.

The Communication Field as a Whole

The 2015 collection, *Transgender Communication Studies: Histories, Trends, and Trajectories,* edited by Leland G. Spencer and Jamie C. Capuzza, is the first book to foreground the intersection of trans studies and the communication field, including essays from communication scholars working within multiple subdisciplines. In his introduction, Spencer reported that his own inspection of communication journals up to that time found roughly 40 articles focusing on trans lives, primarily since 2010. He also located a few book chapters as well as articles written by communication scholars for journals outside the communication field. This edited collection, then, represents trans studies as an emerging research focus within communication. The following overview, organized by subdiscipline, describes some of the trans studies work that has been done in the communication field.

Rhetoric

When the communication discipline began in the early 20th century, it was known as speech communication, with a focus on the study of public speaking. Rhetoric has since become known as only one of many communication subdisciplines, even as the concept of rhetoric has broadened beyond public speaking to include multiple forms of persuasion and influence, both public and private. Communication scholars studying trans lives from a rhetorical perspective have examined the origins and use of trans terminology, cultural constructs of gender in the United States, trans identity categories in public discourse, the act of coming out as trans in a religious context, rhetorical analysis of a 1973 speech by trans activist Sylvia Rivera, and, as noted earlier, the control of gendered bodily sounds made in public restrooms.

Performance Studies

Performance Studies is closely related to rhetoric, but with a greater focus on embodiment and

the public performance of identity. Scholarship in this area has included the conscious and unconscious performance of gender, as well as the examination of nonbinary identities using autoethnography, which is a research method combining autobiography, theory, and cultural situatedness.

Legal Communication

Legal communication includes public courtroom oratory and governmental law but also formal policies within organizations, thus overlapping with organizational communication. Scholars examining laws and policies affecting trans individuals have studied language choices for trans policies in the United States and the United Kingdom, U.S. capital punishment rhetoric, and U.S. asylum requests made by trans immigrants. A 2014 book by communication scholar Isaac West discussed various legal and political issues affecting trans citizens in the United States, including public restroom use and employment discrimination.

Organizational Communication

Much of the trans studies work within organizational communication concerns trans employees in the workplace, and there have been several academic publications on this subject. Organizational scholarship focused on personal interactions in the workplace can also be considered interpersonal communication but tends to be categorized as organizational when the specific structures of an organization affect that communication. Scholars from academic fields outside of communication, such as sociology, have contributed more research on trans experience in organizational contexts.

Interpersonal Communication

Outside the organizational context, interpersonal communication can include interactions among friends, family members, and even strangers. Interpersonal scholarship in trans studies has examined the formation and expression of gender identity, trans emotional and support needs, and the ways in which family members interpret the meaning of a relative's transition, including feelings of stress and/or grief. When interpersonal communication takes place in a medical context, it is generally categorized within the subdiscipline of health communication.

Health Communication

Most of the trans-related health communication research has focused on two areas: doctor–patient interactions and communication regarding safer sex practices. This work has included the trans individual's communication strategies when faced with medical gatekeeping practices, medical practitioners' patient-centered communication with trans adults, and the impact of various forms of stigma on communication among trans women and cis men who have sex with men in South India.

Intercultural Communication

Intercultural communication includes not only communication among nations and cultures around the globe but also communication between cocultures (previously known as subcultures) within one larger culture. Trans scholarship in this area has been largely theoretical, with scholars encouraging more discussion of intersectionality and seeking to combine intercultural communication studies with both trans studies and queer studies. In an essay from Leland Spencer and Jamie Capuzza's 2015 collection, communication scholars Gust A. Yep proposed a research model for "transing" communication within intercultural contexts.

Technological and Mediated Communication

Technological communication is a broad category referring to any form of technology. Radio, film, and television are forms of mass media that communicate messages (such as representations of trans individuals) to an audience who are generally not able to provide feedback through the same media, whereas computer-mediated communication allows for both synchronous and asynchronous communication that can be sent in multiple directions and distributed to multiple locations. Examples include email, text messaging, blogs, and discussion boards. Trans studies in these areas have examined a variety of topics.

Film

Communication scholars have analyzed representations of trans identities in comedic, dramatic, and documentary films depicting both fictional and real-life trans individuals. For example, scholars have suggested that successful film comedies featuring trans characters encourage audience members to see trans individuals as objects of ridicule while identifying with cisnormative identities on the screen. In some cases, scholars have also examined *paratexts,* which are additional materials related to the primary text. In the case of a film, these could include promotional posters, trailers, reviews, interviews with cast or crew members, press kits, soundtracks, DVD special features, and branded merchandise such as toys and clothing.

Television

Trans-related communication studies of television have discussed the depiction of fictional trans characters on scripted series, as well as critiqued the treatment of real-life trans individuals on reality and documentary series. In some cases, scholars have found that depictions of fictional characters have become less stereotypical and more nuanced over time, while particular identity categories, such as nonbinary individuals and trans men, have remained largely absent. Other scholars have found that the pronouns applied to trans individuals have sometimes been based on physical appearance or surgical status, ignoring the pronouns chosen by the trans individuals themselves.

Online

Communication scholars studying trans lives in an online context have analyzed webpages providing trans-related resources for both trans individuals and health care providers, including pages created or maintained by trans individuals and groups. Scholars have also considered how trans individuals seek and locate emotional support online, finding that one's virtual gender expression can have an encouraging effect on one's self-presentation in real life. One article also noted that cyberspace can function in several ways for trans individuals in Israel—as a place to practice experiences before they occur in real life, as a similar social world in addition to real life, and as an alternate world that is very different from real life. Articles examining how online communication can benefit medical transition goals have addressed the use of crowdfunding sites to pay for transition-related surgeries, noting that trans individuals were aware of their own privilege in having consistent online access. Scholars also found that some white transmasculine individuals were conscious of their own privilege with respect to racial appearance and gender expression. The subject of transition was also connected to studies of online images and photographs.

Trans individuals posting photos of themselves changing appearance throughout the transition process were examined, as contrasted with those who offered only pretransition and posttransition images, emphasizing the overall degree of change without revealing the gradual nature of the process. Scholars also analyzed reactions to digital photos of Thomas Beatie, a trans man who chose to become pregnant. It was found that when women viewed a photo of the pregnant Beatie alone in the photo, they found his appearance traditionally masculine but also strange, and they had difficulty believing he was pregnant. However, when they viewed a photo of the pregnant Beatie with his wife, they had a more positive reaction to them as a happy heterosexual couple. Pornographic photos and videos featuring trans performers are also viewed online. Scholars have examined how the consumption of this material has affected attitudes toward trans individuals, and it was found that those viewers who adhered to a conservative political ideology and felt high levels of shame about their own consumption of the materials were the most likely to hold prejudicial attitudes toward trans individuals.

Communication scholars have also examined how images of trans individuals can produce negative reactions in viewers while also strengthening cultural stereotypes. One scholar suggested that film, television, and web producers create trans images that evoke feelings of disgust in the audience for comedic or dramatic purposes, leading some viewers to see violence against trans persons as entertaining. Another scholar analyzed public social media reactions to promotional posters in Austria, finding that artwork depicting a feminine individual with breasts and male genitalia produced a variety of positive and negative responses,

including concern that children were being exposed to the image in a public space.

Some studies of online communication have examined content on the social media site Tumblr. One article considered how trans individuals used the practice of tagging, sometimes resulting in disagreements over the use of normative terms and definitions. Another article discussed the posting of suicide letters by two trans teenagers and the ways in which other Tumblr users engaged in a wide variety of mourning practices.

Community Building

Community building at its core is about people forming connections through practices, programs, and spaces aimed at enhancing the communal bonds of the people united under a commonality. The proliferation of ways to form community—both in person and virtually—have allowed networks of trans people across the world to form and build community through a variety of ways. This entry considers the complex history of community building within this group, along with highlights of community spaces, means to build community, and why community building is necessary for trans people.

A Brief History

Trans people have existed long before there were terms to describe the experience of gender. The term *transgender* can mean different things to different people, as not everyone who transgresses gender identifies as transgender. The term originated in 1971; prior to that, other terms such as *transvestite* and *transsexual* were commonly used to describe the experience of being gender different. *Transgender* as a widely used umbrella term began gaining traction in the 1990s. Trans people were often included under the homosexual/gay umbrella yet faced issues that were vastly different from those of their other queer counterparts.

Through intentional curation of these spaces with other trans individuals, they found a means to navigate systems that were not built with trans people in mind. They found comfort in the ability to empathize with others identified as trans and created support networks and spaces *by* trans people and *for* trans people. One example of this is the 1990 documentary *Paris Is Burning,* in which different drag houses acted as supports for one another while also creating community as a whole through drag balls. Often, individuals within these various houses would live together and support one another through the embodiment of living their true selves, even if that reality was one that society denied or misunderstood.

Community Spaces

Community building can exist within many spaces, but some forms have been particularly prevalent to create affirming and supportive space. Those include community building through in-person and virtual modalities.

In-Person Spaces

Person-to-person and person-to-group environments are what is often thought of as the primary means to build community. Meeting one-on-one, or within a group of whatever size, helps to prevent isolation and loneliness. Community is built in a variety of ways through in-person connections.

Organizations

Organizations play a large role in creating a means to coalesce around a trans identity. Their influence can be twofold: An organization can create in-person spaces for people to create shared information and connection through programs and services that they offer. Some organizations are attuned to specific facets of the trans experience, like the Transgender Law Center in its application to legal issues within trans populations. Depending on their size and role in the community, organizations can reach larger audiences and deal with structural issues that trans people face while also fighting for needs, as do large lobbying groups like the Human Rights Campaign. Organizations can also be small and serve the immediate needs of the direct, local community members, like the Cincinnati-based trans group, Heartland Trans Wellness.

Schools

Schools can also provide spaces and programs focused on connection. Primary, secondary, and postsecondary educational institutions may have a myriad of clubs and student organizations where trans people (i.e., students, staff, teachers/faculty, and administrators) can build connection. And if there is not an organization that supports the needs of queer and trans students, trans students may have the opportunity to start their own club or student organization and have it recognized inside or outside of the school (as an unrecognized club or organization). Such LGBTQIA+ groups and centers host events and groups to further develop bonds within the trans and queer communities that these groups and centers serve. Even within these spaces designed for queer and trans students, most often the individuals who use these spaces the most for community building tend to be from the majority (i.e., white, queer students using the space rather than trans people of color). Gay–Straight Alliances, or GSAs, began in elite, private boarding schools in the late 1980s as a way to help alleviate loneliness, depression, and suicidality that were so prevalent among gay adolescents during this period, and they have shifted to inclusion of trans individuals by renaming these groups Gay–Straight–Trans Alliances (GSTAs). These groups can have a positive impact of building community by providing opportunities for others to come together and feel less alone.

Groups

Groups can also build community. The more common types of groups range from a weekly support group for a small group of trans teens who may be transitioning to a group that is planning activism or a community organizing event. Groups can help disseminate information or solicit engagement and pride around some topic or hobby (e.g., trans gamers, trans people of color support groups). The effect of such groups is intricately woven into the process of community building, as groups provide the means to build rapport, establish empathetic connection with the purpose of the group, and encourage others to learn from one another's experience.

Programs and Events

Programs and events specifically focused on trans communities provide the means to coalesce around trans identities. One example is the annual Philadelphia Trans Wellness Conference, which boasts being the largest free trans conference in the world. Other programs and events can range from large scale (like the Philadelphia Trans Wellness Conference) to small scale (like a local meetup for the Heartland Trans Wellness group based in Cincinnati, Ohio). While the purpose and goals of these groups may vary, they fulfill varying needs of the communities that they serve, provide social spaces to catch up with trans friends and/or colleagues that live in different areas, and establish new connections and networks aimed at promoting community building at large.

Individuals

Individuals are the heart of community building. They provide the social component at the primary foundation of what community building aims to do—connect individuals under a commonality. Although community building is not exclusive to trans people, it is possible to create community within professional contexts (e.g., medicine, law, other professions and fields) and the individuals that one could meet in the process. For example, trans people can meet with a variety of professionals, such as therapists, social workers, educators, doctors, and lawyers, throughout their journey to be fully recognized in their personhood. These professionals could directly identify as trans themselves or can identify as cisgender while still empathizing with the trans communities they help to serve. Some organizations exist for the purpose of creating community around this identity, like the Sylvia Rivera Law Project (SRLP), which provides pro bono legal advice to trans people in New York City. SRLP was started by a trans law professor, Dean Spade, who also identifies as trans.

Online Spaces

In the new millennium, the world has become more closely connected by the Internet and the proliferation of social media. Social media and platforms such as YouTube have created easier access to information from innumerable places throughout the world, so that information and connection are increasingly accessible to most people to consume whenever and however they choose. Online spaces can be used for a variety of purposes—to find information but also to find community, partnership, and even romantic relationships.

Social Media

Commonly referred to as social media, websites and applications that enable users to create and share content or to participate in social networking provide unlimited access to content and community for any and every topic or identity imaginable. Social media have allowed trans communities to stay updated, informed, and connected to the people in their related spheres of influence. It can serve as an inspirational space for trans people to tell their stories, as well as inform them about important legislation and its potential impact on their livelihood. Virtual spaces can demystify and destigmatize the transition process and living as a trans person. Although these experiences are not representative of every individual's unique process, they do help to decrease the feelings that they are the "only one" within their immediate sphere and provide immediate access to other trans people across the globe.

YouTube

One platform that provides a wealth of information, as well as personal stories within the social media sphere, is YouTube. The same can be said for other social media platforms such as Facebook and Instagram; however, YouTube also provides a free platform for trans people to tell their stories however they choose through vlogging, or video blogging. Some trans people document their gender transitions openly for others to follow and learn from their experiences. YouTubers such as Gigi Gorgeous or Jazz Jennings have opened up new possibilities for people wanting to learn more about the process of transitioning—things that they have to deal with, parts of their process, who and how they date people, or even the ways that they navigate tough topics or subjects. Platforms like YouTube enable community building by destigmatizing and legitimizing ways to be trans, thereby creating virtual kinship networks (e.g., a close relationship with another over the Internet).

YouTube videos from all over the world and from all types of trans perspectives and identities are represented. One prominent YouTuber, NikkieTutorials, came out as a trans woman in January 2020, and the video in which she discloses her trans identity has over 34 million views at the time of this writing. Nikkie is able to build community with her followers, cis and trans, by engaging with comments and questions, doing follow-up vlogs, and being open and out about her experience as a trans influencer. YouTube represents a substantial means of connection and exposure to trans people and their lives.

Dating Apps

Another means of connection and community building, albeit not necessarily the focus of these applications, is online dating apps. Applications such as OkCupid, HER, Grindr, and a host of others recognize trans people on these dating and meetup platforms. Trans people who are interested in dating only other trans people can state that they are "T for T," or "trans for trans," to indicate that this is their choice. Although dating apps are not necessarily considered community-building tools, the ability to delineate "T" and "trans" allows others to find other trans people within these platforms and, potentially, find community as a result—like friendships and other types of nonromantic relationships. Individuals on these platforms are not restricted by how and where they can use these apps to build networks and/or community within them.

Importance of Building Trans Community

Trans people make up a small subculture within the total world population, and this population is difficult to measure with current data collection models. Within the United States, as of June 2016, the Williams Institute estimated the U.S. trans population at approximately 0.6% of adults, or 1.4 million individuals. The trans community is not monolithic in terms of lived experiences or identities claimed. Differences exist within local, regional, and national levels, as well as individually. Every trans identity is unique, and no two people will have the same history or other identities that can intersectionally affect their experiences and their access to power. This is precisely why forming bonds under the trans umbrella can be so important to provide people with support, community, love, and hope for the future. The same can be true with other minoritized aspects of identity, such as race or sexuality. People form community around places where they share something special, and trans people are no different from others in that respect. As with other minoritized identities, trans people require community building as a resilience strategy to deal with oppression and disproportionate power dynamics that exclude them from participation in certain aspects of everyday life. Likewise, some community-building efforts can create kinship networks for trans people who do not have access or support through family of origin bonds. Chosen kinship networks help support trans people through trusted trans friends, who are considered as valuable as family-of-origin relationships and, in some cases, more valuable. Overall, these bonds formed through community-building efforts (large and small) contribute to greater well-being, resilience, wisdom, and connection with other trans people. Community can literally be lifesaving.

Compton's Cafeteria Riot

The Compton's Cafeteria Riot of August 1966 is one of the first known instances where trans and gay people collectively resisted arrest to protest police mistreatment. In the Tenderloin district of San Francisco, California, drag queens fought back against police officers attempting to remove them from Gene Compton's Cafeteria, a 24-hour restaurant, and place them under arrest. Although this event predates the Stonewall Riots by almost 3 years, it is not well known. The riot served as a catalyst for other organized protests in San Francisco, but it did not spark the ongoing protests and later national marches that occurred after Stonewall.

Drag Queens Fought Back Against Police

The riot took place in August 1966; the exact date is not known because the event received no news coverage, and police records of the event no longer exist. The riot began in the early morning hours, when the police arrived at Compton's to remove the drag queens and sex workers who gathered there. Some accounts say that the riot began when a police officer grabbed someone, who then threw coffee. Patrons began to fight back against the police by overturning tables, throwing dishes through the large windows, and striking officers. First-person accounts recall the patrons using handbags and high heels against the police with their batons. The police retreated to the street and the patrons followed, continuing to fight back. Those arrested were placed in paddy wagons, while others damaged at least one police car and some nearby businesses.

Under the excuse of laws against "female impersonators," the police of this era had free rein to target, beat, arrest, and detain individuals who were perceived as men dressing in traditionally women's clothes. Trans women were taken out of bars and restaurants or off the streets of the Tenderloin, put in police vans, and driven around. Some were taken to jail, subjected to strip search, and forced to have long hair cut or be imprisoned. In 1962, the police had appointed Elliot Blackstone, a sergeant in the San Francisco police department, as a liaison to the then-called homophile community, and he worked to abolish laws such as those forbidding "female impersonation" but with little success.

Tenderloin District in the Late 1960s

Compton's Cafeteria was located at the intersection of Taylor and Turk streets, in the Tenderloin neighborhood of San Francisco—part of a small chain of diner-type restaurants that served affordable food 24 hours a day. Situated on a busy corner, Compton's had large windows and room for about 60 customers. It was next door to a gay bath house and near a bar and a discount store. Compton's served as an informal gathering place and community center for the neighborhood as well as the main dining option for the residents of nearby hotels and boarding houses. The Tenderloin was San Francisco's "red light district"—with its many bars and clubs, as well as hotels for rent by the hour. In the 1960s, it was home for trans women, drag queens, and gay men (often called gay hustlers at the time) with ethnic diversity—many supported themselves as sex workers. In the mid-1960s, the Tenderloin district was one of the most affordable areas of San Francisco, which was being gentrified—consigning poor people into smaller areas.

The Compton's Cafeteria Riot occurred in the societal context of San Francisco in the mid-1960s, which included anti–Vietnam War protests and "free love" social movements, which included a rejection of stereotypical, rigid gender roles and expectations of male dress and grooming. Many military personnel, passing through San Francisco on their way to Asia, came to the Tenderloin for entertainment. The publication in early 1966 of *The Transsexual Phenomenon* by Harry Benjamin, a physician who provided medical transition treatment in San Francisco, had begun to exert an influence on conventional views about gender identity. The vision of transitioning was part of the atmosphere in the time that led up to the riot. Also a factor in the Tenderloin was the Glide Memorial Methodist Church, with leaders who had worked on Black civil rights. Glide's street ministry reached out to the neighborhood, focusing on support for poor people and building connections with the trans, gay, and drag communities—providing a foundation for community organizing.

Vanguard was a trans/drag/gay organization that was initially formed through the Glide Church and held meetings at Compton's Cafeteria. Compton's charged LGBT people fees for sitting and tried other methods to forestall the restaurant from becoming an informal community center. Management at Compton's Cafeteria began trying to remove customers, including Vanguard members who were meeting, and sometimes called the police. On July 18, 1966, and subsequent nights, Vanguard members picketed Compton's, protesting about being removed. After the protests, Compton's increased calls to the police. The growing tensions boiled over on the night of the riot.

After the riot, Compton's shut at midnight and closed entirely in 1972. Some reported that police harassment and arrests for "female impersonation" decreased after the riot, and organizing for LGBT rights continued. The San Francisco Health Department began to provide services to trans people, including identification cards with their gender at a time when official documents could not be changed. This opened educational and professional opportunities to some who had been present during the riot. Access to medical alignment increased.

Remembering the Compton's Cafeteria Riot

Based on the work of historian Susan Stryker, the documentary *Screaming Queens: The Riot at Compton's Cafeteria* (2005) is credited with bringing these nearly forgotten events into LGBT history. In 2006, a historical marker was placed at the site of Compton's Cafeteria on the 40th anniversary. In 2016, one block of Taylor Street was renamed Gene Compton's Cafeteria Way, and other events celebrating the 50th anniversary of the riot were held. San Francisco designated the neighborhood as Compton's Transgender Cultural District in 2017, the world's first such district to be recognized.

The Compton's Cafeteria Riot was incorporated into the fictional TV show *Tales of the City* (2019). Photos of the character Anna Madrigal in front of Compton's Cafeteria are part of the story, and two other characters are filmed with the historical plaque. One episode of the show re-creates parts of the riot, with influences from the real event mixed with fictional characters.

Consensual Nonmonogamy

Consensual nonmonogamy is an umbrella term that includes a broad range of relational structures that are not monogamous and that are practiced with the knowledge and consent of all parties involved. Trans and/or nonbinary people, like cis people, engage in a variety of relationship structures, including those grouped under this term. Consensual nonmonogamy is a vast umbrella that ranges from traditional nonmonogamous practices, such as polygamous religious marriages to more recent relational structures such as polyamory and relationship anarchy. As long as all parties involved are capable of, and consent to being in, a nonmonogamous relationship, their relationship(s) can be described as falling under consensual nonmonogamy.

Consensual nonmonogamy is not a new concept. In fact, on a global level, nonmonogamy is widespread across cultures, classes, and religious traditions. Even though polygamy, or the practice of having more than one wife, is more common, polyandry, which is the practice of having more than one husband, also exists in countries such as Tibet and Nepal. Polygamy and polyandry are usually, and often, illegal in current geopolitical states, but many people have never stopped practicing these customs. These relational structures can be found across religious traditions, from Islam to Christianity to Indigenous spiritual practices. Some might argue that some of these relationship structures, especially within polygamy, are not consensual because of the inherent power differentials, especially with regard to gender, and the cultural pressures that people with less power—usually, but not exclusively, women—are subject to. However,

the same could be said of almost any relationship structures across the globe, including cis heterosexual marriages.

Some people involved in more recent and Western-based relationship structures, such as polyamory, have distanced themselves from forms of traditional consensual nonmonogamy, such as polyamory and polyandry, both because of the critiques mentioned previously but also because of the religious and/or culturally specific aspect of these practices. Many people engaging in more recent and Western-based relationship structures use the umbrella of ethical nonmonogamy to distinguish their practices and to indicate the intention of being both consensual and ethical in their practices. Others find adding "ethical" to be unnecessary and even to come across as judgmental, as it seems to imply that the forms practiced by the people using this adjective are inherently superior to other forms of nonmonogamy.

The most well-known forms of consensual nonmonogamy in Western dominant culture are swinging and polyamory. Swinging is seen by most people who participate in it as a leisure activity. People can engage in swinging by themselves or as a couple. Usually swinging is focused on sexual behaviors, such as group sex or exchanging partners between couples, and any romantic involvement outside of established couples is frowned upon. However, sometimes swingers engage with the same group over a long period of time and long-term friendships do arise within swinging communities. Polyamory, meaning many loves, on the other hand, is the practice of having multiple romantic, and at times sexual, relationships. *Polyamory* can also be considered an umbrella term since people who practice it engage in a range of relationship structures. For example, people might define their relationships as an open marriage or an open relationship, and they might use various models for these, from hierarchical polyamory to relationship anarchy. Swinging is most commonly practiced by cis heterosexual people, whereas polyamorous communities often include a broader ranges of gender identities and sexualities.

Relationship anarchy is based on applying anarchist principles to romantic and/or intimate relationships. In fact, relationship anarchy questions the way in which dominant culture views relationships by challenging the supremacy of romantic and/or sexual relationships over other forms of intimacy. People engaging in relationship anarchy usually value nonhierarchical relationship structures, autonomy, and interdependence and do not believe the state should control or oversee relationships through practices such as marriage. This and similar frameworks have informed the rise of new umbrella terms such as *contemporary intimacies* along with *consensual nonmonogamy*. The difference between those terms is that contemporary intimacies encompass relationships that are not just romantic and/or sexual, such as relationships based on kinship or concepts such as queer families and families of choice.

As stated initially, trans and/or nonbinary people can engage in any relationship structures, as do their cis counterparts. However, many trans and/or nonbinary people who are also deeply steeped in queer communities and culture might be more familiar with consensual nonmonogamous relational structures than are their cis counterparts. Given the historical lack of recognition of queer relationships by geopolitical states, queer communities have, in fact, often practiced less normative relationship structures in Western dominant cultures. This means that, even though they might be monogamous themselves, many trans and/or nonbinary people are likely to know people in broader LGBTQIA+ communities who do practice, or have practiced, some form of consensual nonmonogamy. Some authors have also written about the intersection of trans identities and nonmonogamous relationships. In fact, Dossie Easton and Catherine Liszt (1997), in their influential book on nonmonogamy, discuss transgender identities as an antecedent to nonmonogamy. Even though there is little to no research about trans people and nonmonogamous relationships, some authors have found that there is a higher prevalence of this relational structure within trans and/or nonbinary communities.

Whether we consider more recent and Western-based forms of consensual nonmonogamy or more traditional and/or religion-based ones, this umbrella term clearly indicates that monogamy is not the only relational structure available both historically and in present times. It is also important to remember that *consensual nonmonogamy* is a vast umbrella term that encompasses a range of relationships that might be based on similar

practices yet highly different values. *Contemporary intimacies* might also be a more apt umbrella term to encompass those forms of consensual nonmonogamy that invite us to think of relationships outside of a framework that privileges romantic and/or sexual relationships as inherently primary. Regardless of the terminology used, people engaging in consensual nonmonogamy might also parent within these relationship structures in ways that might be more or less open depending on whether they find it safe to do so within the geopolitical areas where they live. Parenting within consensual nonmonogamous relationships does not differ greatly from parenting within monogamous relationships except that there may be more adults involved. The latter might, of course, also occur within monogamous relationship structures in the case of blended families.

Cooper Do-nuts Riot

The Cooper Do-nuts Riot was a May 1959 trans protest against police harassment that took place at the Cooper Do-nuts in downtown Los Angeles. Like the uprisings at Dewey's restaurant in Philadelphia in April and May 1965, Compton's Cafeteria in San Francisco in August 1966, and the Black Cat Tavern in Los Angeles in January 1967, the Cooper Do-nuts Riot is considered significant to LGBT history as one of a number of trans protests against police harassment that predated the Stonewall Riots in New York City in 1969. Like these other actions, limited evidence has meant that the riot at Cooper's has been subject to historical debates about who was involved (trans women, racial minorities) and how that involvement shapes our interpretations of the modern LGBT rights movement. Beyond its role in LGBT social movement history, the Cooper's riot reveals how gender and sexual nonconformity has been linked to patterns of social stratification and policing of urban social space, as well as how after-hours spaces of cross-gender intimacy and sexual commerce have operated as sites of rebellion against these racialized, gendered, sexualized, and capitalist modes of policing and segregation.

Despite its importance to historical understandings of the modern LGBT rights movement, the Cooper's riot was not documented in the historical record. In 2005, gay Latino writer John Rechy, who was present at the riot, recounted the events of the night to journalist and historian Stuart Timmons. Rechy recalled how two police officers from the Los Angeles Police Department (LAPD) raided Cooper Do-nuts, an all-night coffeehouse in downtown Los Angeles. On the

night of the riot, the officers circled the block a few times, parked, and entered Cooper's, demanding to see identification and stating no reason for their harassment. Patrons began throwing doughnuts at the cops, then paper cups, coffee-stirring sticks, and anything else they could get their hands on. The officers retreated, returning to their cars to summon backup. The police cordoned off the block and arrested and jailed many of the rioters.

The LAPD honed these tactics of violence, harassment, and abuse by policing Black migrants who arrived in Los Angeles in large numbers in the late 1930s and 1940s. LAPD's shift toward statistical policing and crime prevention in the 1950s also meant that police enforcement was often heaviest in racial minority communities, especially Latinx neighborhoods. LAPD's vice squad increasingly targeted gay and lesbian people through these racialized structures of policing. In the Cold War context of the 1950s, LAPD targeted Cooper's as a place patronized by known and suspected homosexuals. Because it was located in downtown Los Angeles on a "seedy" stretch of Main Street between two of L.A.'s older gay bars, police cars regularly patrolled the area. Officers often made arrests based on the penal codes for lewd vagrancy, sex perversion, and prostitution-related offenses. Its location at the converging sites of outlaw genders and sexualities and racialized poverty doubly marked Cooper Do-nuts for policing and surveillance.

The police also surveilled Cooper Do-nuts because it was frequented by an ethnically mixed crowd of drag queens and male hustlers, many of them Latinx or African American, along with the people who enjoyed their company or bought their sexual services. The night of the riot, police officers demanded identification from coffeehouse patrons, targeting those whose appearance might not match the name or gender designation on their IDs. While drag queens may have been the most conspicuous in this regard, the illicit activities of other patrons meant their identification may not have aligned with their documentation. Producing documentation also could have increased already criminalized patrons' risk of policing and incarceration. According to Rechy, after the police began rounding up targeted patrons, others in the restaurant began to resist the police. While the immediate cause of their resistance might have stemmed from police's harassment and arrest of drag queens, the collective resistance of other patrons suggests that their doughnuts were aimed at broader structures of carceral state power.

While the clientele of Cooper Do-nuts and the neighboring gay bars were not mutually exclusive, the discriminatory admission policies of some gay bars based on appearance and identification rendered the mixed crowd at Cooper's available for further police scrutiny. Indeed, gay bars often discriminated against criminalized patrons like drag queens, hustlers, and vagrants because they brought with them increased police surveillance. The illicit sexual economies and cross-racial, class, gender, sexual affiliations at the coffeehouse marked it as what Shane Vogel calls a scene of "criminal intimacies" that "thrive[d] beyond the threshold of closing time and exist[ed] within the temporality of after-hours."

It is as an earlier scene of criminal intimacies that the riot at Cooper's precedes the Stonewall Riots in New York City in 1969. In her only public interview on record, Black trans sex worker Marsha P. Johnson discusses the shift in the Stonewall Inn's clientele in the years before the riots. The bar first admitted women, then drag queens, and developed a reputation as a space where drag queens could work without the fear of arrest. As one of the first drag queens to frequent the Stonewall Inn, Johnson recalled how its changing reputation as an after-hours space of cross-gender intimacy and sexual commerce subjected patrons to increasingly violent and invasive forms of policing. Previously, patrons were lined up and asked to leave, but according to Johnson, the night before the riots, "every single body" was searched by the police because the place "was supposed to be closed, and they opened anyway." The Cooper Do-nuts Riot predates the Stonewall Riots not so much as an earlier moment of identity-based rebellion but as another after-hours space of criminal intimacies with the potential to resist intersecting forms of carceral state power.

Cox, Laverne

Laverne Cox is an African American trans actor, model, dancer, and trans rights activist who is one of the most prominent voices within the trans community, especially among trans women of color. This entry briefly chronicles Cox's early life before discussing her acting career, history of activism, and honors and achievements.

Early Life and Education

Cox was born on May 29, 1972, in Mobile, Alabama, where she and her twin brother (musician and performance artist M Lamar) were raised by their mother and grandmother. From a young age, she was regularly bullied by her peers for being feminine and not fitting into the gender expectations for someone assigned male at birth. When she started having feelings for boys in sixth grade, she did not know how to deal with the situation and attempted suicide. Cox survived through finding a home in the arts and studied creative writing and dance at the Alabama School of Fine Arts, a residential high school. Cox attended Indiana University before transferring to Marymount Manhattan College, where she graduated with a bachelor's degree in dance. While at Marymount, she became involved in acting, appearing in numerous plays produced by the school's theater department and performing in drag shows in New York City nightclubs. Cox never identified as a drag queen, but the performances gave her a chance to act and present publicly as female while she began to medically transition. Through performing, Cox met and formed a community with other trans women of color, which helped her to live her life as a Black trans woman.

Acting Career

Cox made her television debut in 2008 on *Law & Order: Special Victims Unit* and VH1's *I Want to Work for Diddy,* a reality show in which contestants competed for employment as an executive assistant to music mogul Sean "Diddy" Combs. Cox was the first out African American trans woman to appear on a reality TV show. Cox's popularity prompted VH1 to offer her an opportunity to launch her own show, which became *TRANSform Me,* a makeover series in which Cox and two other trans women, Nina Poon and Jamie Clayton, responded to "fashion emergencies." In 2013, Cox began playing the character of Sophia Burset on the hit Netflix series *Orange Is the New Black (OITNB),* a comedy-drama about the various interpersonal relationships, alliances, conflicts, and power struggles between women serving time in prison. Cox's portrayal of Burset earned her numerous honors, including three Primetime Emmy Award nominations, a Critics' Choice Television Award nomination, and two Screen Actors Guild Awards for "Outstanding Performance by an Ensemble in a Comedy Series." Other notable roles have included portraying Dr. Frank-N-Furter in the 2016 tribute to the 1975 cult classic *Rocky Horror Picture Show* and appearing on *Doubt, The Mindy Project, Curb Your Enthusiasm,* and *A Black Lady Sketch Show.*

Activism and Education

Cox's advocacy for the rights of trans people is also notable. In 2014, she produced *Laverne Cox Presents: The T Word,* an MTV documentary about the experiences of seven trans youth from across the United States. The film won a Daytime Emmy for "Outstanding Special," making it the first trans show and Cox the first out trans woman producer to win an Emmy. Cox's advocacy also brought significant attention to the case of CeCe McDonald, a Black trans woman who was imprisoned for defending herself against a physical attack by a white supremacist. Cox produced a documentary, *Free CeCe!,* which chronicled

McDonald's journey through the criminal justice system and raised awareness of the high rate of violence perpetuated against trans women of color. Beyond producing documentaries, Cox has also used her celebrity status to speak out in support of the trans community and on trans rights issues. One notable instance occurred when Cox and another trans woman, actor and model Carmen Carrera, were asked invasive questions about gender-affirming surgeries by veteran television journalist Katie Couric while the women were guests on Couric's show. Cox responded by saying,

> I do feel there is a preoccupation with that. The preoccupation with transition and surgery objectifies trans people. And then we don't get to really deal with the real lived experiences. The reality of trans people's lives is that so often we are targets of violence. We experience discrimination disproportionately to the rest of the community. Our unemployment rate is twice the national average; if you are a trans person of color, that rate is four times the national average. The homicide rate is highest among trans women. If we focus on transition, we don't actually get to talk about those things. (McDonough, 2014, n.p.)

Cox's refusal to answer the question and redirection of the interview's focus demonstrate how other trans people who are asked invasive questions can respond without shutting down the conversation altogether. Furthermore, Cox's response reveals why it remains critically important to interrogate the structural manifestations of oppression that collude to expose LGBTQIA+ people to relentless socioeconomic, political, cultural, emotional, spiritual, and physical violence. Cox was honored as a "Woman of the Year" by *Glamour* magazine in 2014, and the accompanying article included a quote about Cox's influence by Couric, who was a previous "Woman of the Year" recipient.

Honors and Achievements

Cox's visibility in the media has made her a trailblazer and brought much greater attention to the experiences of trans people. Among her many achievements, she was featured on the cover of *Time* in 2014, making her the first openly trans person on the magazine's cover. That same year, she appeared on the cover of *Essence* magazine, alongside Black female actors Alfre Woodard, Nicole Beharie, and Danai Gurira, and in 2018, she became the first openly trans person to be featured on the cover of *Cosmopolitan* magazine. She was also included in *Essence*'s 100 Most Influential People in 2015 and on the "Power Lists" of *Ebony* and *Out* magazines in 2014 and 2017, respectively. Due to her creative prowess and relentless advocacy, Laverne Cox remains one of the most recognizable and influential Black trans women in the United States.

Criminal Justice System

Criminal justice systems have fundamentally affected the lived experiences of trans people. Since the beginning of the LGBTQ+ rights movement, advocates have sought to prevent violence against trans people, including by seeking to decriminalize nonconforming gender identities and expressions, eradicate police mistreatment of trans people, abolish prisons, and reduce the array of harms trans people experience at the hands of criminal justice systems. Today, while trans people are increasingly recognized for contributing to political change benefiting both trans and cis people, scholarship has aimed to reposition the

criminal justice experiences of trans people from the margins to the centers of important criminological conservations and related social action.

Since before the 20th century, criminalization of trans people has influenced scholars and activists to address laws and norms that have led to widespread violence against trans people. Trans criminalization has taken the forms of prohibiting clothes other than the ones typically worn by the gender one was assigned at birth, punishment for certain kinds of relationships based on a person's gender, and other laws targeting the lives and livelihoods of trans people. Throughout Europe and the United States, doctors, lawyers, social scientists, and scholars sought to reform these laws by arguing that transgender identities and expression are normal and unharmful. The work of these early advocates for trans rights was influential in catalyzing a worldwide movement to improve the lives of trans and other gender-nonconforming people.

"The first pride was a protest"—a statement that acknowledges the collective demonstrations protesting police targeting and criminalization of trans and queer people in the 1960s—has increasingly gained traction in contemporary discussions on the origins of the LGBTQ+ movement. Before and after the Stonewall Riots, led in part by trans activists who resisted police targeting and arrest, groups of activists seeking to improve the lives of trans people in the United States set decriminalization of gender-nonconforming identities and expressions as a principal goal for the movement. Over the course of the 20th century, the United States began to abandon these laws as a direct result of these trans activists and their legacies.

In the 21st century, however, criminalization imposed on countries through colonization continues to affect trans people. On the African continent, as well as throughout Eastern Europe, a resurgence of punishment for gender- and sex-related crimes threatens the safety of people who transgress gender norms. A worldwide uptick in trans-related hate violence and increased enforcement of anti-trans laws underscore the relationship between criminal justice–related action and lived experiences of trans and other gender-nonconforming people.

To respond to widespread violence directed toward trans communities, lawmakers internationally have instituted trans-related hate crime laws aiming to reduce bias-motivated violence. These laws punish perpetrators of anti-trans violence by increasing their prison sentences and other sanctions. Despite the proliferation of these laws, statistics of violence against trans people continue to be troubling. For example, trans women in the United States are more than four times more likely to be murdered than other women, and among all known trans homicide victims from 2013 to 2016, 93% were trans women of color. Relatedly, police mistreatment of trans people makes reporting of trans-related violence to police problematic—an issue that is compounded by risk factors for becoming a target for anti-trans abuse, such as sex work. As a result, hate crime legislation has been an insufficient solution for some of the world's most vulnerable trans victims of violence, many of whom fear being arrested alongside their perpetrators.

Additionally, scholars and activists observe that the spread of hate crime laws contributes to the expansion of prison systems, which disproportionately affect trans people, particularly trans people of color. Empirically speaking, hate crime laws lengthen the prison sentences of convicted offenders, increase criminal sanctions, and expand police and prosecutorial powers to enforce the law. These measures unequally affect communities of color, including trans people of color, who are incarcerated at higher rates than the rest of the population. In a large sample of transgender women in the United States, nearly one fifth of respondents reported having been imprisoned at some points in their lives. While in prison, many trans people are at a greater risk of harm than the rest of the prison population, with 47% of previously incarcerated transgender women having experienced violence, and among trans women, trans women of color were the most likely to be victimized.

In 2016, these realities resulted in a statement by the United Nations Subcommittee on Prevention of Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment, which in an official report criticized the conditions of confinement for trans prisoners. The report noted that violence against trans people "is exacerbated in situations of deprivation of liberty" and

> with very few exceptions, State officers are not trained to understand the needs

> of . . . transgender [people . . .] and there are no institutional policies and methods to adequately address self-identification, classification, risk assessment and placement. (United Nations Committee Against Torture, 2016, p. 13)

These issues have spurred calls for prison reform, as well as prison abolition, in light of the immediate dangers of imprisonment for trans people.

Historically and throughout the world, criminal justice systems have targeted and unfairly treated trans people. Since trans people first began speaking up about the societal conditions that put them at significant risks of violence, criminalization has been considered a central obstacle for trans lives. Today, the plight of trans people who interact with criminal justice systems has fueled a resurgence in awareness of the negative impacts of these systems on trans people worldwide. While many countries have decriminalized trans identities and expressions, as well as instituted hate crime legislation punishing anti-trans violence, these measures have proven insufficient in eradicating the oppression trans people experience at the hands of state actors. These failures pose present and future challenges for criminal justice systems in the United States and around the world, making trans issues a significant topic of discussion—and action—for criminologists, advocates, and criminal justice officials.

Crossdressers as Part of the Trans Community

Individuals who crossdress have always been a part of the trans community and, in fact, were instrumental in the formation of the trans and the larger LGBTQIA+ rights movements. Although some crossdressers do not align themselves with the larger trans community, most do, and they have historically been among the most prominent members of the community. The crossdressing population may be less visible today, but they remain important contributors to many trans social and political groups.

The First "Trans" People

Individuals who presented as a gender different from what they were assigned at birth first began to be described as "trans" by the pioneering sexologist Magnus Hirschfeld, who coined the word *transvestites*—from the Latin *trans* or "across" and *vestis* or "clothing"—in his 1910 book with that title. Unlike many of his contemporaries, Hirschfeld recognized that transvestism was not a form of psychopathology, nor were most of those who engaged in crossdressing attracted to others of the same sex or doing so for erotic pleasure. These men and sometimes women were simply more comfortable, and experienced a greater sense of well-being, when dressed and expressing themselves as a member of the "opposite" sex. They did not desire to change their assigned sex (which distinguished them from trans women and men) but wanted to exhibit traits and mannerisms not traditionally associated with individuals of their sex.

While Hirschfeld saw *transvestite* as simply a descriptive term for a minoritized gender group, it began to become a derogatory word in the 1970s

and 1980s. Individuals with no understanding of the crossdressing community redefined "transvestites" as men who were turned on by wearing traditionally women's clothing. In response, members of the community started to refer to themselves as "crossdressers," and this remains the appropriate term today.

Early Crossdresser Activism

Some of the earliest trans activists were crossdressers. Because crossdressing was against the law in many U.S. cities, individuals who were thought to be crossdressers were often harassed and arrested by the police, which was a contributing factor to the Stonewall Riots in New York City in 1969. Some of the participants in the riots were self-identified transvestites, including Sylvia Rivera and Marsha P. Johnson. Soon after Stonewall, they established Street Transvestite Action Revolutionaries (STAR), a grassroots group that supported and fought for the rights of the many young trans people who were living on the city's streets. At the same time, two other New York City crossdresser activists, Lee Brewster and Bunny Eisenhower, founded the Queens Liberation Front and led a campaign that decriminalized crossdressing in the city. Brewster also began *Drag*, one of the first politically oriented trans publications, in 1970.

Despite helping to start the LGBTQIA+ rights movement, crossdressers, as well as drag queens, were largely exiled from the movement by the mid-1970s because many radical lesbian feminist leaders considered female-presenting crossdressers to be demeaning to women, and many moderate gay male leaders saw crossdressers as taking away from the mainstream respectability that they sought for themselves. Nevertheless, crossdressers continued to engage in activism and organized within the trans community. Two groups for heterosexual crossdressers and their wives and partners merged in 1976 to form the first national trans organization in the United States, the Society for the Second Self or Tri-Ess. While Tri-Ess's membership was primarily crossdressers, it welcomed all trans people, and its leaders were involved in many trans rights events and initiatives. For example, Tri-Ess representatives served on the board of directors of the International Foundation for Gender Education (IFGE) and helped found the Southern Comfort Conference, one of the largest annual gatherings of trans people, in 1991.

Contemporary Crossdresser Activism

In recent decades, crossdresser activists have had significant involvements in both the LGBTQIA+ and trans rights movements. Crossdressers participated in the 1987 National March on Washington for Lesbian and Gay Rights and the 1993 March on Washington for Lesbian, Gay, and Bi Equal Rights and Liberation, despite the latter denying a motion by trans activists and supporters to have "transgender" included in the name of the march. Many crossdressers also attended the annual International Conference on Transgender Law and Employment Policy (ICTLEP) in the 1990s and were among those who founded the annual National Gender Lobbying Day in 1995 and continued to participate each year.

WPATH Recognition

The Standards of Care developed by the World Professional Association for Transgender Health (WPATH) beginning in 1979 have historically focused on trans women and men and not included crossdressers and other trans people, because transitioning individuals were seen as needing a consistent means to access hormones and surgeries. But the attention given to the medical care of trans women and men was largely the result of the work of Louise Lawrence, a full-time crossdresser who educated Alfred Kinsey, Harry Benjamin, and many other medical professionals and scientists about the experiences of trans people. She also introduced many trans people to sympathetic doctors and to each other.

Not until 2019 did crossdressers receive official recognition from medical professionals. In that year, at the conference of USPATH, the U.S. chapter of WPATH, crossdresser activists met with association leaders, which led WPATH to agree to use terminology that was inclusive of crossdressers, to expand its trainings of providers to include crossdressing information, and to appoint a non-transitioning trans individual to the USPATH board to ensure that the concerns of crossdressers were being included in the group's work in the

future. After years of being overlooked as members of the trans community, crossdressers had finally received some of the acknowledgment that they desired and deserved.

Crossdressing, History of

Crossdressing has a long and rich history with clear relevance for trans studies. Across centuries and over continents, countless individuals have engaged in crossdressing to communicate desires, identities, and ways of being that challenge fixed binary gender. Crossdressing practices are diverse, however, with multiple cultural meanings that historians need to carefully explore. This entry examines the complexity of crossdressing as a concept, the range of crossdressing practices in history, and efforts to police crossdressing in the 19th- and 20th-century United States through crossdressing laws.

Conceptualizing Crossdressing in History

Histories of crossdressing occupy an important but fraught place within trans studies. In part, this is due to the complexity of crossdressing as a concept. On one hand, crossdressing describes a set of clothing practices that can be central to trans experiences—that is, wearing clothing to communicate a gender identity that diverges from the one assigned at birth. On the other hand, the concept rests upon a problematic set of assumptions that historians need to interrogate and not reproduce.

First, the term *crossdressing* assumes that the gendered meanings of clothing are relatively stable and rooted in cultural consensus. In reality, such meanings are the products of social struggles and shift significantly over time. In 18th-century Europe, for example, upper-class men typically wore makeup and wigs, engaging in dress practices that would strike contemporary observers as feminine; these practices, however, did not accrue such meanings until the 19th century. Moreover, the changing meaning of clothing often involved significant social struggle and conflict. For example, in the United States during the second half of the 19th century, the question of whether women should be permitted to wear pants was hotly debated in city courtrooms and newspapers, as women asserted their legal right to wear men's clothing following arrests under local crossdressing laws (discussed in more detail below). Even present-day associations of blue clothing with boys and pink clothing with girls used to be the other way around in the early 20th century. The shifting meanings of gendered clothing demonstrate that crossdressing practices can only be analyzed through close attention to their specific historical context.

Second, the concept of crossdressing rests on the assumption that gender identities are fixed and immutable, permanently tied to the sex assigned at birth. Trans identifications, past and present, negate this assumption. In doing so, they undermine the conceptual logic of crossdressing, as clothing and identity can be aligned even when identity and the sex assigned at birth are not.

Finally, crossdressing as a concept naturalizes the binary model of sex and gender, assuming that all people, regardless of historical or cultural context, can be accurately classified as one of two discrete sexes or gender. Binary sex and gender, however, are Western cultural products, and multiple societies have organized sex and gender differently. Most notably, in the U.S. context,

Indigenous peoples have recognized multiple gender categories beyond the man–woman binary. When European explorers first encountered these practices in the 16th century, they refused to acknowledge their specific meanings, reducing them instead to crossdressing and responding with violence. In 1513, for example, Spanish conquistadors executed 40 native people in Panama for wearing women's clothing on bodies they deemed male and for engaging in sodomy. Gendered violence remained integral to settler colonialism over time, even as the forms of its expression changed. During the 19th century on the northern continent, for example, the federal Bureau of Indian Affairs pressured people who lived on reservations to abandon their native gender presentations and adopt clothing and hairstyles that conformed to white binary gender norms. As these examples suggests, crossdressing histories need to move beyond acknowledging the cultural specificity of binary sex and gender to foreground the ways that its development was inextricably linked to colonial terror and violence.

Even within binary sex–gender systems, the term *crossdressing* operates as a fluid signifier with numerous cultural meanings. Crossdressing does not refer to one specific style of dress but to a wide range of clothing worn by multiple people for varying reasons. Additionally, these meanings shift significantly across historical contexts, and competing meanings emerge even within specified time periods. Consequently, scholars need to take care not to assume symmetry between past crossdressing practices and contemporary meanings. In particular, modern sexual identity categories, such as lesbian, homosexual, and heterosexual, did not arise until the late 19th century, while contemporary gender identities, including transsexual and transgender, emerged even later in the second half of the 20th century. Imposing contemporary sexual and gender identities onto past crossdressing practices exemplifies the methodological problem of presentism: the historical inaccuracy of squeezing past experiences into contemporary categories. Histories of crossdressing need to pay close attention to the social and subjective meanings of these practices, both to shed light on the past and to gain insight into the ways that contemporary understandings of gender normativity and difference emerged.

Crossdressing Practices in History

Scholars have documented a long and rich history of crossdressing practices. Most evidence of these practices can be found in legal records, newspapers, antivice investigative reports, and sexology texts. There are far fewer first-person accounts of crossdressing in the historical record, and consequently, it is difficult to pinpoint how people understood their own dress practices in their own terms. Nonetheless, several sets of motivations can be identified, which could exist independently or overlap.

Historians have uncovered many cases of people who lived and dressed in a gender that diverged from the one assigned at birth, in ways that resemble present-day trans experiences. Some of these people entered the historical record upon their death. In mid-19th-century California, for example, a stagecoach driver named Charley Parkhurst identified and lived as a man for 30 years until a coroner classified his body as female after his death. Similarly, in the 1870s, a Mexican woman named Mrs. Nash worked as a laundress for General Custer's Seventh Cavalry at Fort Lincoln in Dakota; when she died in 1878, the medical examiner observed her body and announced that she was male. Sexology texts also include multiple case histories of people who expressed gender identities that may be comparable to today's trans identities, particularly Magnus Hirschfeld's classic text, *The Transvestites,* published in 1910.

Historians have also documented thousands of cases of women who dressed as men during the 18th and 19th centuries for practical reasons. Some did so as a temporary measure to escape or evade state-sponsored institutional violence. During slavery in the American South, for example, some enslaved Black women wore men's clothing as a disguise when fleeing captivity as part of the underground railroad. Decades later, in the early years of anti-Chinese immigration laws that targeted women over men, some Chinese women wore men's clothing to stow away aboard ships and evade immigration inspectors when they entered the United States.

Many other women donned men's clothing to access economic resources and employment opportunities that would otherwise have been unattainable. Some worked as sailors, others enlisted in the

military, and more still worked as farmers, drivers, or stable-hands or tramped across the country in search of work during economic downturns. In the United States, crossdressing enabled women to participate in major historical events that were the province of men, fighting in the Civil War, for example, and seeking their riches during the predominantly male California gold rush.

Dressing as men also gave women access to recreational spaces, such as bars and nightclubs, that they could not access otherwise, and in the late 19th century, these dress practices became a recognized cultural trend in major urban areas. During the same period, some feminists also took up dress reform as a political issue, arguing for women's right to wear clothing traditionally reserved for men.

Historians have also documented long associations between crossdressing and nonnormative sexual practices. In 18th-century London, for example, some people assigned male at birth congregated at taverns or coffeehouses called Molly Houses; many of these patrons wore women's clothing, used women's names, and sought the social and sexual companionship of men. In the United States, urban sexual subcultures developed slightly later, but by the 1890s, several major cities were home to vibrant vice districts that included bars and clubs catering to a nascent queer and trans community. These included The Dash bar in San Francisco, which featured female impersonators who had sex with men for money on the premises, and Paresis Hall in New York City, which catered to people assigned male at birth who dressed as women and desired sex with men. Paresis Hall was also the meeting place for the Cercle Hermaphroditos, an organization that advocated for the rights of "androgyne" people who identified as a sex different from that assigned at birth. These commercial spaces were joined by private parties and balls, including risqué drag balls in Washington, D.C., attended by African American men in women's clothing, as well as an infamous drag party in Mexico City, in 1901, which ended in a police raid and legal case that captured the nation's attention.

Nonnormative gender and sexuality also came together in 19th-century street-based sex work. In 1850s San Francisco, for example, some female sex workers wore men's clothes to advertise their availability for commercial sex, while in New Orleans, some women prostitutes adopted men's names. Other sex workers, assigned male at birth, dressed and identified as women. Historians, for example, have documented the case of Mary Jones, an African American woman in 1830s New York City, who was arrested by police on charges related to prostitution and subsequently classified as legally male.

Crossdressing practices also have deep roots in theater. In mid-16th-century Japan, for example, Kabuki theater first emerged as a women-only show, with some actors performing in men's clothing. When women were banned from the stage in the 17th century, these gender dynamics flipped and men-only casts took hold, with some men wearing women's clothing. During the same period, in European Elizabethan theater, young male actors regularly crossdressed to perform as women characters, while in the 18th century, women actors wore men's clothing to perform in breeches roles. In China, male and female actors shared the stage through much of theater history, but male casts dominated Cantonese opera during the 19th century and crossdressed to play women's roles. In the 19th century, migration brought some of these cultural practices to the United States. In 1870s San Francisco, for example, theaters in Chinatown predominantly staged regional Cantonese operas that featured male actors performing in women's roles and clothing.

In the United States, theatrical crossdressing achieved widespread popularity in the mid-to-late nineteenth century through minstrel shows and vaudeville. Minstrel shows gained popularity during the 1840s, as all-white male performance troupes parodied African American music and dance, frequently appearing on stage in stereotypical blackface makeup. In these spaces, cross-gender performances dovetailed with racial mockery, as white men impersonated African American women for comedic effect.

Toward the end of the 19th century, vaudeville supplanted minstrel shows as the nation's most popular theatrical form. From the vaudeville stage, gender impersonators became household names, receiving top billing and national acclaim. The biggest celebrities were female impersonators, such as Julian Eltinge and Bothwell Browne, but male impersonators like Vesta Tilley and Kitty Doner

were also stars. Vaudeville gender impersonation differed from earlier crossdressing roles in American theater, in that it intended to convincingly portray the impersonated sex, rather than function as a comic device. At the turn of the century, vaudeville was viewed as wholesome family entertainment, but by the 1920s, it was stigmatized as immoral theater as gender impersonation became increasingly associated with homosexuality. Historical documents also reveal that crossdressing took place in amateur theatrical productions, sometimes in unlikely locations. These included German detention camps at the end of World War I and U.S. prisons, as well as within elite organizations that catered to wealthy white men, such as Harvard University's Hasty Pudding Club and San Francisco's Bohemian Club.

Beyond the stage, crossdressing was also a regular feature of more participatory entertainments, such as the festivals and carnivals of early modern Europe that temporarily inverted the social order. At these events, the poor dressed as the wealthy, the powerless as royalty, and men and women as each other. Similar crossdressing practices also took place at masquerade balls in 18th-century Europe and 19th-century United States, allowing participants the temporary thrill of disguise without seriously undermining gender hierarchies.

As this review suggests, a wide range of crossdressing practices took place in the past with competing and sometimes contradictory meanings. Some of these practices reinforced binary gender norms, particularly those associated with mainstream entertainment and theatrical performance. In contrast, crossdressing practices that communicated nonnormative gender identities or sexual desires posed a fundamental challenge to dominant norms and often triggered harsh punishments. In the United States, these punishments primarily occurred via crossdressing laws.

Crossdressing Laws in History

As a set of practices that frequently challenged dominant gender norms, crossdressing was subjected to intense regulation through law. In the United States, local crossdressing laws operated as a popular tool for policing gender and sexual transgressions from the 1840s to the 1970s. At least 34 cities adopted crossdressing laws in the mid-19th century, beginning with Columbus, Ohio, in 1848. Another 11 cities followed suit in the early 20th century, as did several other cities in the 1950s, including Detroit, Michigan, and Miami, Florida.

Crossdressing laws varied in their approach to criminalization. The majority banned men or women from appearing in public when "wearing a dress not belonging to his or her sex" or "wearing the apparel of the other sex." Some city laws also targeted crossdressing in private places, and some exclusively focused on the clothing of those assigned male at birth. Other cities and a handful of states also criminalized "indecent dress" or the wearing of "disguises." In 1845, for example, New York State passed an antidisguise law, in response to rural workers who disguised themselves as women and/or Native Americans when engaging in political protests. In 1874, a similar law in California criminalized "masquerades" in response to gambling saloon dealers who wore wigs and masks to avoid identification by undercover police. These laws were not explicitly concerned with crossdressing, but they were nonetheless used to arrest people who wore clothing that diverged from their legal sex.

During the 19th and 20th centuries, crossdressing laws were used to harass, arrest, and incarcerate people for a wide range of crossdressing practices. These included women who wore men's clothing for practical and/or political reasons, people who crossdressed to signal their same-sex desires, and people who used clothing to communicate an identity that diverged from their assigned sex. Thousands of people were arrested for the crime of crossdressing. Those apprehended faced police harassment, public exposure, and legal punishments ranging from minimal fines to lengthy jail sentences.

At the turn of the 20th century, some crossdressing practices accrued new social meanings as markers of psychopathology, particularly when used to communicate cross-gender identifications. As a result, many people who were arrested under crossdressing law during this period were sent to psychiatric institutions instead of jails. In 1895, for example, police arrested a person in New York City's Central Park for wearing women's clothing on a body that the law classified as male, sending her to the psychiatric wing of Bellevue Hospital for

sexual abnormality. Similarly, in 1917, Los Angeles police arrested a man named Jack Bee Garland, classified him as female, and locked him up in a state psychiatric institution, where he refused to wear women's clothing as required by law. For some people, psychiatric institutionalization was a life sentence. In 1890s San Francisco, for example, a person named Dick/Mamie Ruble was sent to the state insane asylum after insisting that they were neither male or female, following their arrest under crossdressing law. Ruble remained there for 18 years, before dying in 1908 of tuberculosis.

By the early 20th century, crossdressing law operated in tandem with federal immigration law to punish crossdressing offenders. Several policy initiatives facilitated this development. First, from 1891 onward, federal immigration law permitted the deportation of any noncitizen found guilty of a range of "morals" offenses, and some people were deported following a crossdressing arrest. In San Francisco, for example, a young woman named Geraldine Portica fell afoul of this policy in 1917 and was deported to Mexico, following her arrest for wearing women's clothing on a body the law classified as male. Second, beginning in the early 20th century, states began to routinely deport noncitizens who were held in psychiatric institutions, including those institutionalized for their crossdressing practices. Finally, federal immigration law also banned people with nonnormative gender presentations from entering the United States. In the early 20th century, for example, immigration officials at New York's Ellis Island denied entry to Otillie Castnaugle in 1902 and Alejandra Velas in the 1910s for wearing clothing that did not match the sex assigned at birth.

By the mid-20th century, crossdressing law had become a key tool for policing lesbian, gay, and transgender communities. Crossdressing practices were far more visible than same-sex intimacies and hence easier to target during street policing and bar raids. For example, when police raided queer bars in the 1950s and 1960s, they routinely used crossdressing laws to harass and arrest butch lesbians and gay men in drag. Police also used crossdressing laws to harass trans people. Firsthand accounts of this period describe police using a "three items of clothing" rule to guide enforcement, requiring people to wear three items of clothing of the "correct sex" or face arrest. Police photographs document arrests and raids in multiple cities, including Chicago, San Francisco, Los Angeles, and New York City, while police statistics reveal that hundreds of people were arrested in major cities each year.

By the 1970s, however, the days of crossdressing law were numbered, triggered by persistent community resistance, in combination with broader legal, cultural, and political trends. In particular, three developments came together in the mid-1960s to undermine the viability of crossdressing law.

First, the emergence of grassroots resistance in queer and trans communities highlighted an increasingly collective refusal to tolerate harassment. This activism did not occur in a vacuum, but it emerged in the context of broader political upheavals and widespread social movements, including the Black Power movement, Chicano movement, second-wave feminism, gay liberation, and a radical antiwar movement. During the 1960s, in major American cities, police harassment under crossdressing law helped sparked collective resistance and a new militant phase of trans and queer activism, including the 1966 Compton's Cafeteria Riot in San Francisco and the 1969 Stonewall Riots in New York City.

Second, the 1960s witnessed the development and popularization of gender-ambiguous fashions, as the hippie youth counterculture linked a politics of nonconformity to androgyny, with men wearing long hair and frilly shirts and women wearing men's jeans and tapered shirts. These fashions challenged a foundational assumption of crossdressing law—that clothing clearly belonged to one of two sexes—and undermined its viability. Indeed, in some cities, such as Cincinnati, Ohio, and Columbus, Ohio, the popularity of gender-ambiguous clothing prompted judges to overturn crossdressing law as unconstitutionally vague, since men's and women's clothing could no longer be meaningfully distinguished.

The emergence and institutionalization of the new identity category of "transsexual," in the mid-1960s, troubled the logic of crossdressing law in an even deeper way. After all, crossdressing law not only rested on the assumption that clothing could be easily identified as belonging to one of two discrete sexes but also on the more fundamental assumption that people could be similarly neatly classified. In the 1960s, the insistence that

gender identity could diverge from the sex assigned at birth began to gain legal credibility, as protests against crossdressing law attracted new levels of support from some medical experts, such as Harry Benjamin. Benjamin's standards of care for the medical treatment of transsexuals required individuals seeking surgery to first live as the "opposite" sex. This set the stage for courtroom battles in which doctors accused the state of interfering with their treatment protocols and demanded the repeal of crossdressing laws. At least some state courts accepted doctors' claims, and local crossdressing laws were repealed on these grounds in Columbus, Ohio; Chicago, Illinois; and Houston, Texas.

Dating

Dating refers to the process through which individuals meet and spend time with each other for the purpose of assessing compatibility for pursuing a romantic relationship. Also referred to as courtship, specific dating rituals and traditions vary considerably as a function of historical time period and culture. In general, dating often involves social activities that help two (or more) people to get to know each other, often with the degree of intimacy increasing as the duration of the dating relationship progresses.

Since the advent of the Internet, some forms of dating now take place online, where individuals can sign up for online dating websites that serve a "match-maker" role in helping people to find other individuals with similar interests who are seeking various forms of romantic relationships. LGBTQIA+ individuals were early adopters of online dating, as it provided a greater sense of safety by providing the opportunity to learn more about a prospective partner before meeting them in person. This extra layer of security has been particularly important to trans individuals, as it allows for technology-mediated disclosures of identity. Disclosure of a trans identity within the context of dating can be dangerous given the pervasive cisgenderism and transphobia that remain within society. Research on trans dating is sparse and has primarily explored the ways trans individuals navigate their dating worlds with respect to disclosing their trans identity at various time points within the dating process. Additionally, research has also examined the availability of prospective partners for trans individuals. This entry reviews key themes in this research, namely, the process of disclosing one's gender identity to prospective dating partners, the exclusion of trans people from the dating world, experiences of dating violence, and suggestions for future areas of focus.

Disclosing Trans Identities While Dating

Heteronormative cultural biases and a strong investment in the gender binary result in trans individuals having to navigate an additional layer of identity disclosure when entering the dating world. All individuals seeking romantic partners must navigate a plethora of choices concerning which aspects of their identity to share and at what stage. For example, single parents may give thought as to when to let prospective or current dating partners know about their children. Some parents may opt to make this information available upfront in order to avoid investing time in partners who are not open to dating single parents, while others may wish to delay disclosure of parental status until further into the dating relationship in order to allow them the opportunity to be seen as who they are first and a parent second. Similar considerations are made for a variety of issues, including divorced status, personal habits such as smoking or skydiving, or even musical preferences. There are few aspects of an individual's identity, however, that upon disclosing could result in a significant threat of harm. Due to high societal levels of

transphobia and cissexism, the disclosure of a trans or nonbinary identity can serve as a potential catalyst for social rejection and violence, including lethal violence. Thus, decisions concerning when, to whom, and how to disclose a trans identity within the context of dating are important and carefully considered by many trans individuals.

To help mitigate the potential for negative reactions to in-person disclosure, many transgender individuals make use of online dating sites and apps. Yet, even online, individuals must consider how they will disclose their identity. Some choose to proactively disclose by including their identity in the written portion of their dating profile. On the dating app Grindr, it is possible to list oneself within the transgender "tribe" as a means of disclosing identity. Others have discussed how they use their profile pictures to provide information about their gender identity, with some nonbinary or genderqueer individuals being sure to provide photos that represent the spectrum of their gender presentations. Research on proactive disclosure of gender-diverse identities indicates that such disclosures meets multiple goals. Doing so provides a sense of certainty that the individuals who contact them will already be aware of their identity, thereby allowing trans individuals to avoid spending time communicating with individuals who would otherwise not be interested in dating a trans or nonbinary individual.

While some trans dating app users indicate that proactive disclosure helps to create a sense of authenticity within their online profile, others prefer to disclose their identity after already contacting prospective partners. Delaying disclosure can serve to help frame the aspects of their identity that they feel are more salient to their sense of self, such as their personality or interests. Choosing to disclose after contact can also serve a more practical purpose: avoiding online harassment. Even within an online environment, many have reported that disclosing a trans identity on a dating profile often results in targeted online harassment. For example, many trans women have been told to leave Grindr by gay men who see the app as being exclusively for cis gay men.

Public disclosure of a trans identity can also result in being fetishized. Trans-sexualization or fetishization refers to viewing trans individuals purely as sexual objects to serve the fulfillment of others' sexual fantasies. Understandably, such views can hinder the development of genuine romantic relationships, and thus many trans individuals opt to disclose their identity in private conversations. Notably, however, it is often still seen as important to disclose such an identity prior to meeting someone in person in order to avoid the potential for in-person rejection or even violence.

In cases where individuals meet in person, such as at an event or a bar, other strategies must be employed concerning disclosure of one's gender identity. The extent of such considerations may vary by context and goals; for example, the difference between seeking casual encounters versus enduring relationships may alter an individual's perceived need to disclose their gender identity. Decisions about whether and when to disclose may also be shaped by an individual's body. For example, trans individuals often report wanting to be confident that a prospective sexual partner is aware of what genitals to expect and may thus time an in-person disclosure accordingly when they have not been able to disclose to someone prior to meeting them. It should be noted that the perceived imperative that trans individuals disclose their identity to prospective dating partners is symptomatic of the heteronormative and cisnormative society in which we currently live.

Dating Partners

One of the reasons that this disclosure can be so daunting is that very few cisgender (cis) people report a willingness to date trans individuals. Indeed, a 2019 study found that 87.5% of cis individuals surveyed would not consider *hypothetically* dating a trans individual. Heterosexual cis individuals surveyed were the least likely to report a willingness to consider trans partners (3.1%). Within LGBTQIA+ communities, the percentage of individuals willing to consider dating a trans person was reportedly higher, with 23.9% of cis gay and lesbian men and women reporting a willingness and 55.2% of queer, two-spirit, and bisexual individuals reporting being open to dating trans partners. Thus, trans individuals are faced with the decision of disclosing upfront and significantly narrowing their field of potential partners

or take the risk of disclosing after already meeting someone.

Indeed, research has found that simply being told that someone is trans influences how cis individuals rate that person in terms of attractiveness. One novel study showed a sample of 319 cis men and women a series of 48 photos that had been *randomly* labeled with respect to trans, nonbinary, or cis status. The results were striking, in that the photos labeled as trans were rated significantly less attractive than the cis-labeled photos, with nonbinary photos falling in between. The photos used were of cis men previously rated as highly masculine and cis women previously rated as highly feminine, yet the mere label of trans or nonbinary altered perceptions of attractiveness.

But who do trans people find attractive? An area of interest to relationships researchers who study dating processes is the question of mate selection—or, more colloquially, to whom are people attracted? Traditionally, this research has focused on the patterns of attraction typical to cis men and women and is often rooted in an evolutionary perspective, which seeks to understand how evolution and the need to procreate may have shaped dating behaviors and preferences. One study has explored mate selection in a trans sample by asking trans men and women about the characteristics they value most in prospective dating partners. The study was also interested in determining whether an individual's sex assigned at birth or their current gender identity proved to be a stronger predictor of their mate preferences, based on previous research that has categorized preferences by biological sex in cis samples. Among trans men and women, the researchers found that the most valued characteristics were mutual attraction/love, satisfying sexual relationship, dependable character, pleasant disposition, and sociability. The least valued characteristics were chastity, similar religious background, similar political background, and similar education. When comparing the characteristics valued by trans men versus trans women, trans women placed more value on satisfying sexual relationships, good looks, good health, favorable social status, greater financial prospects, and being ambitious and industrious. In other words, trans women displayed mate selection preferences typically found in both cis men (satisfactory sexual relationship, good looks) and cis women (financial prospects, social status, ambition).

Dating Violence

Although there is a tendency to think of dating as an exciting experience that opens the door to the potential for future romantic relationships, many aspects of dating can be risky. It is important to take precautions when meeting strangers, even if they are known by mutual friends, and this may be even more important for trans individuals. Dating violence is any form of interpersonal violence, including physical, psychological, and sexual, that occurs within the context of a dating relationship. Trans individuals are at an increased risk of experiencing dating violence. One study reported that 45% of a sample of trans youth between the ages of 16 and 24 had experienced some form of intimate partner violence in their lifetime. Trans individuals who have experienced more transphobic victimization in their lives are at an increased risk of experiencing intimate partner violence, as are individuals who have sex work experience. In a broader study of dating violence within the LGBTQ+ youth community, trans youth were more than twice as likely to experience violence from an intimate partner compared with cis sexual minority youth.

Conclusion and Future Directions

Most of the academic literature on romantic relationships has excluded the experiences of trans individuals. The research that does exist tends to focus on the negative aspects of trans dating experiences, such as the lack of available partners, safety concerns related to disclosure of identity, and the risk of intimate partner violence. Even among these topics, more knowledge is needed, such as how trans individuals navigate in-person disclosures when dating and the varied risks associated with differing strategies. Moving forward, research should also examine the extent to which disclosure remains an issue in decades to come, as greater inclusion and acceptance of trans individuals may render such disclosures either unnecessary or less dangerous. The existing research focus on more negative aspects of trans dating experiences is symptomatic of the

current state of trans experiences within a cissexist and transphobic society. Future research should explore the opportunities that trans relationships and dating experiences provide for developing more nuanced understandings of gender and the role that gender plays in romantic relationships. Research that explores sources of resilience within the context of trans dating experiences as well as research on prejudice reduction within the context of dating apps and websites should also be prioritized.

Death and Dying

Death typically refers to the end of life of a person or organism. The medical definition of death is when an individual has sustained either (1) irreversible cessation of circulatory and respiratory functions or (2) irreversible cessation of all functions of the entire brain, including when the brainstem is dead. Dying, then, is the gradual cessation of existence or function in an individual. There is a large literature on death and dying in cisgender people. There is much less research on trans people’s experience of dying. For trans people, dying and death can take on more complex definitions and meanings. This entry explores some of the facets of death and dying in the trans community.

For cisgender individuals, the traditional challenges of end of life (EOL) are well documented. Among these challenges are organizing legal papers, last wishes, religious/spiritual needs, death certificates, final funeral needs, and postdeath support for the family. For gender-nonconforming persons, these EOL challenges can be significantly difficult and may come with some significant risk to the dying trans person. In addition, there are aspects of a trans person’s life that have no analogy in the cisgender population.

Dying and Death in the United States

For patients and their loved ones, no care decisions are more profound than those made near the end of life. For the millions of U.S. Americans who

work in or with the health care sector—including clinicians, clergy, caregivers, and support staff—providing high-quality care for people who are nearing the end of life is a matter of professional commitment and responsibility. These individuals have a responsibility to ensure that end-of-life care is compassionate, affordable, sustainable, and the best quality possible. In *Dying in America,* a 2015 consensus report from the Institute of Medicine (known today as the National Academy of Medicine), a committee of experts found that improving the quality and availability of medical and social services for patients and their families could not only enhance quality of life through the end of life but may also contribute to a more sustainable care system. The challenge here is that these reports are based upon what might be called traditional family structures and binary sexed/cisgender identities. For trans persons, even the cisgender end-of-life challenges can be extremely difficult. For trans individuals, one of the most difficult things to confront is dementia.

Estimates of Prevalence and Incidence of Dementia

To understand the prevalence and incidence of dementia in the trans-identified population, we first briefly review the literature on Alzheimer's disease (AD) and general dementia presence both in the United States and in the global population. In 2013, as many as 44.4 million people were estimated to be living with dementia, increasing to 75.6 million by 2030. A threefold rise in the number of people with Alzheimer's disease is expected to occur between 2000 and 2050. AD is the most common cause of dementia, accounting for two thirds of the cases of dementia. AD is the sixth leading cause of death in the United States, with estimates that one in three seniors die of AD or another type of dementia. For people over the age of 65, AD is the fifth leading cause of death.

Estimating the Prevalence of Trans Dementia

We can make only best-guess estimates of population sizes to assist us in estimating the current and future prevalence of dementia in these populations. Given this diversity of elders in the general population, the same might be expected for the general trans-identified population. Tarynn Witten, a scholar of trans aging, estimates that there are over 20 million trans-identified people worldwide, with trans adults aged 65 years and older estimated at between 4.1 million and 12.3 million. Using Witten's estimates on the prevalence of trans/gender-nonconforming identities in the United States, we estimate that as of 2025, there will be between 19,788 and 126,566 trans persons with AD. By 2050, the number of trans-identified persons with AD is estimated to be between 26,399 and 170,010. It is important to remember that trans population estimates are likely an underestimate and that with the appearance of younger and younger cohorts, the number of trans elders is likely to increase by 2050. (These estimates do not include estimates for other forms of dementia such as vascular dementia or Pick's disease.)

Reasons for Concern Over Trans Dementia and AD

Surveys of trans people point to the importance of the trans identity and the fear that trans persons have of dementia in general and of AD in particular. The struggle to attain one's true gender identity is rife with difficulties, among them social isolation, decreased independence and capacity for decision making, increased vulnerability to LGBTQ-related stigma, and exposure to unsafe social and physical environments.

Because Alzheimer's disease is a terminal and a progressively worsening disease, individuals will eventually need some caregiving followed by eventual 24-hour caregiving. This caregiving can occur in the home or in assisted-living facilities but will eventually likely be in some form of nursing home or other 24-hour nursing facility. Fear of how they will be treated by caregivers, particularly as AD takes away their trans identities, is a fear so great that many of Witten's respondents indicated that they had plans to commit suicide before they would progress into dementia. Work by a number of other research groups, among them Karen Fredriksen-Goldsen's group (scholars in LGBTQ aging) and Katherine Kortes-Miller's group (scholars in EOL issues among LGBTQ people), has also provided insights into the fears and experiences of trans people as they age and approach the end of life.

Other Factors Surrounding the End of Life

Many factors affect the end-of-life experiences of trans people. Major challenges exist around respect for the identity of the trans person, as well as quality of care and respect for the postdeath wishes of the trans person. Prior to death, trans people may worry about how they and their families will be treated after their death.

Closing Thoughts

Up to this point, the discussion has focused on the death and dying of an individual. However, for trans persons, other forms of death have no analogy in the cis population: deadnaming and dead-to-me.

Deadnaming

When trans persons transition, they change their names to match their new identity. Many of them no longer want to recognize their birth name. If someone uses this birth name, instead of the new name of the individual, it is called *deadnaming*. *Deadnaming* occurs when someone, intentionally or not, refers to a person who is transgender or gender nonconforming by the name they used before they transitioned. You may also hear it described as referring to someone by their "birth name" or their "given name." Deadnaming is one of the many microaggressions that nonbinary individuals must address. Deadnaming can also occur when the birth name is used on the death certificate, on a grave marker, or during any religious/spiritual ceremonies.

Dead-to-Me

There are two major ways in which the "dead-to-me" phenomenon can occur. The first happens when the trans person's family expels the trans person from the home or the family. This is a particular problem for many young trans, including nonbinary, persons. When older individuals transition, however, their family members can simply no longer consider them part of the family. This leads to a dead-to-me scenario. This is not uncommon in today's elder trans people's lives. An alternative dead-to-me scenario is when a transitioned trans individual simply shuts off all aspects of their former life, friends, family, and job. They will not acknowledge old friends or family, and they often quit their job and go job hunting in their new identity so that nobody knows about their past.

Decisions to Parent

Parenthood is an important developmental milestone. Although some trans people decide to remain childfree, the majority of trans people want to become parents—although the if, how, and when can be complex. It is estimated that between 25% and 75% of trans people want to become parents. Biological or genetic parenthood can occur through sexual intercourse or with the use of assistive reproductive technologies, such as being or using a sperm or egg donor. In addition, trans people can become parents through adoption, foster care, or blending/stepfamilies. Each of these options comes with unique challenges and barriers for trans people, which play a role in the decision-making process and the attainment of future parenthood.

Many trans people describe a strong desire for biological parenthood—yet biological parenthood is not always possible or preferred. The majority of young trans people describe adoption or foster care as the way they will attain parenthood in the future, although this varies across gender identity. Trans women are more likely to want to become parents through adoption, while gender-nonconforming people, nonbinary people, and trans men are more likely to desire biological parenthood. While there are a number of ways that trans people can become parents, decisions regarding future parenthood are driven by a number of factors, including reproductive accessibility (availability and functionality of sperm, eggs, and/or uterus), personal preferences, and financial resources.

For biological parenthood, accessibility depends on an individual's or couple's availability and functionality of sperm, eggs, and/or uterus. In many countries, such as in Europe and Asia, trans people are subjected to laws and policies that require forced sterilization, resulting in the loss of the possibility of biological parenthood. These policies and practices are no longer standard in the United States. With advancements in reproductive technologies, multiple avenues for biological parenthood are now available. The use of hormone therapy and gender affirmation surgeries, which are unique to trans people, adds complexities to biological family creation. For example, hormonal therapy for those assigned male at birth can decrease the quality and quantity of sperm, with long-term impacts on future fertility being largely unknown. For those assigned female at birth, hormone therapy often results in an absence of menstruation, making conception difficult or impossible. If an individual is taking hormones, these medications need to be discontinued for 2 to 6 months, in order to attempt conception. Often trans people are unaware or uninformed regarding these potentially negative impacts on future fertility. Even when well informed regarding the possible risks of these medications or surgeries on fertility, many prefer the positive gains of these therapies on their physical and mental health.

With advancements in reproductive technology, trans people have the option of fertility preservation, such as controlled freezing of sex cells (sperm or eggs) or reproductive tissue, which could provide the option of biological parenthood in the future. Ideally, fertility preservation would occur prior to beginning hormonal therapy, although this is not always possible. As discussed earlier, if an individual were already taking hormones, medications would need to be discontinued during the fertility preservation process. Many trans people are uninformed regarding fertility preservation options, although among those who are aware, the majority decline. The most common reasons for declining fertility preservation are not being able to afford the process for extracting and/or storing sex cells, lack of insurance coverage for these procedures, not wanting to delay or stop gender-related therapies, and the reproductive capabilities of their future partner.

For those who choose to preserve sex cells or stop hormonal medications, becoming a parent biologically is still dependent on several factors. For trans people, stopping hormonal therapy may not fully restore reproductive capabilities and often results in undesired body changes. For the individual with a uterus, becoming pregnant creates physical and psychological discomfort, such as the feminization of the body, making this method undesirable. For those with partners assigned female at birth, the use of donor sperm and the partner's uterus in order to conceive is a preferred method for becoming a parent. If a uterus is needed to conceive biologically, surrogacy could be used. Surrogacy is a less common method owing to its being extremely expensive and, for many, financially impossible. It is important to note that many of these family planning options are expensive, not typically covered by health insurance, and complex legally and psychologically.

Although some prefer biological parenthood, most envision this pathway as undesirable or impossible, with most describing adoption or foster care as their ideal way to become a parent. Many trans people describe becoming parents through adoption or foster care as a way to give back to the wider community and to help children in need of a loving home. In addition, trans people discuss being more open to adopting "higher risk" children, such as older children, children with special needs, or those who identify as LGBTQ, which are all groups disproportionately represented in the child welfare system. Even with this great need for adoptive and foster parents, especially for "high-risk" children, trans people lack basic legal protections against gender-based discrimination by child welfare agencies. This lack of legal protection allows agencies to refuse to work with, deny potential placements, or deprioritize these potential parents on the basis of gender identity. Even with these barriers, adoption or foster care is the preferred method of becoming a parent among trans people, but owing to discrimination, misinformation, and lack of basic legal protections, this pathway is not always possible.

Many trans people want to become parents, but there are a number of barriers and challenges associated with if and how they will do so. Because of unethical forced sterilization policies, negative impacts of gender-related therapy on fertility, and a lack of accessibility to fertility preservation, biological parenthood can be impossible or unattainable. The majority of trans people see adoption or foster care as their ideal pathway to parenthood. Owing to a lack of antidiscrimination policies, however, there are a number of challenges that trans people are faced with and need to navigate when deciding to become parents through adoption or foster care. The eradication of discriminatory practices and policies, more public education regarding fertility, and the establishment of gender-related nondiscrimination policies would ensure that trans people can make informed decisions regarding future parenthood.

Demographics of the Trans Community

In 2011, the Institute of Medicine (IOM) issued a report calling for additional demographic

information on gender minorities, noting that basic demographic data, "which are critical to understanding and meeting the needs of populations, are lacking for LGBTQ populations. From the data that are available, much more is known about lesbians and gay men than about bisexual and transgender people." As detailed in the IOM's report, a number of barriers have led to a relative absence of demographic research on trans people. This can be attributed to the limited academic and public attention paid to trans (i.e., not cis) people, as well as the related lack of representative data on trans people.

In recent years, however, demographers have begun to challenge gender-normative and heteronormative assumptions that are inherent in the ways that we collect data about populations, as well as the type of questions that we ask. This shift has paved the way for demographic research on LGBTQ people as a whole. The past 10 years, for example, have produced greater insight into the demographic characteristics of LGBTQ people. This research has been important to gain better understanding of questions such as health, income, families, and spatial distribution of non-heterosexual populations. In addition, however, this research has brought attention to the ways that many of our survey questions or demographic models are framed by normative assumptions surrounding gender. As discussed in this entry, this body of work has the potential to push demographers to rethink our approaches to fundamental questions, such as the relationship between gender and migration, morbidity, and labor market outcomes.

Although research on the demography of gender, as well as the demography of sexual orientation, has made demographers more cognizant of how gender plays an important role in demographic outcomes, most scholars continue to primarily use a binary understanding of gender. Several factors contribute to this narrower interpretation of gender. First and foremost, nonbinary understandings of gender—that is, understandings of gender that acknowledge and interrogate gender identities outside of and beyond "male" and "female"—have escaped public attention prior to recent years. As a result, the public has not demanded information that would drive both research and funding on trans, including nonbinary, people. In addition, on the majority of representative surveys, gender is captured through a binary "sex" variable. Given that demographers primarily rely on such surveys, they have been without data to examine many demographic outcomes.

With shifting public and academic attention, there has been a greater demand for research on the trans population, and in some cases, researchers have made changes to survey questions in order to allow for more inclusive research. These changes have resulted in demographers engaging with many population-based questions about trans individuals for the first time. And, in 2019, the Population Association of America included the first session focused on trans people.

This growing body of research is exciting but in many respects has been fairly limited in focus. A great deal of the scholarship to date has examined the best way to capture gender on surveys and how results might vary dependent on the measurement used. Outside of this work, there has been some research, drawing on representative and/or large sample size surveys, that has described some of the demographic characteristics of trans individuals. Questions about gender that go beyond the male–female binary have been included most extensively in surveys about health. This has resulted in much of the demographic literature on trans people being focused on health outcomes.

This entry summarizes some of the key findings across three major areas: measurement of gender on surveys, demographic characteristics of trans people, and health outcomes. The entry focuses primarily on data collected within the United States but incorporates findings from other countries as well as regional variation within the United States. The entry also takes a broad approach toward demographic research and includes some studies that draw on qualitative data and/or nonrepresentative surveys. These decisions were made in order to include population research in an emerging field with more limited data availability.

Measuring Gender

Given that gender has been conflated with biological sex (itself problematically viewed as binary), researchers have typically relied on survey questions asking respondents whether they are male or female in order to analyze the effects of gender on

demographic outcomes (e.g., the U.S. Census surveys, the General Social Survey). As potential respondents are increasingly requesting options that go beyond male and female, as well as willing to provide such responses, researchers have weighed options of the best way to assess trans identities. Questions about how to measure gender in a nonbinary fashion have been given the greatest attention in the population-based literature because if researchers agreed to consistently use a single measure of gender, this would allow for across-survey comparisons on outcomes, including, for example, how geographic region shapes the way that gender identity interacts with questions such as fertility or relationship formation. For example, research has shown that same-sex couples living in the U.S. South are more likely to have children than those living in other regions of the country. The presence of better data on trans identity might enable us to find similar (or perhaps quite different) geographic patterns in parenthood. Relatedly, there is a great deal of variation in what states require to change gender identity on birth certificates. This has implications on many levels, but prior to the Supreme Court's 2015 decision legalizing same-sex marriage, birth certificate variation generated regional differences in marriage for some couples.

The Williams Institute at the University of California–Los Angeles (UCLA) Law School has been one of the leading voices in identifying the best practices for measurement of sexual orientation and gender identity. In 2013, in collaboration with a group of scholars, policymakers, and transgender leaders, the institute published a best-practices guide on measurement to promulgate the addition of these questions to a greater number of nationally representative surveys. In their report, they discussed four popular approaches that have been used to measure gender identity.

The first approach entails a two-step process whereby survey respondents are asked the sex that they were assigned at birth on their birth certificate and also asked their current gender identity. The current gender identity question provides options beyond the binary, adding choices such as trans male/man, trans female/woman, genderqueer, and a fill-in "other" category. This two-step approach allows researchers to identify whether someone who answers that their current identity is male was once female, given that many individuals choose to identify with one of the binary choices rather than a transgender or genderqueer option. Thus, without the birth certificate question, these individuals would be classified as cisgender male and not included in analyses that seek to examine outcomes for individuals who no longer identify with their sex assigned at birth. This two-step approach is used on some instruments by the U.S. Centers for Disease Control and Prevention (CDC) and has been shown in studies to produce the most accurate information regarding gender identity and to increase the identification of transgender individuals.

The second approach for measuring gender is a single-item question. In 2007, Massachusetts added a single-item question to its Behavioral Risk Factor Surveillance System (BRFSS) survey, which is a CDC and state department of health collaborative survey covering key health issues. The survey covers specific diseases or ailments, such as diabetes, cancer, HIV/AIDS, and others; preventive behaviors such as exercise, nutrition, and health care visits; and risk behaviors such as smoking, sun exposure, alcohol and drug use, and number of sex partners. The proposed question on trans identity provided a definition of transgender identity and then asked the respondent whether they considered themselves to be transgender and provided the options of male to female, female to male, gender nonconforming, and no. Initially, the included question asked only whether an individual considered themselves to be transgender (yes/no), but the full question was later incorporated that added a variety of choices. This single-item question produced relatively consistent results across states but does not have the added validity of sex assigned at birth. Without information on sex assigned at birth, it becomes difficult to validate whether an individual who identifies as male is cisgender or now identifies as male but was assigned female at birth. As noted before, not including this pairing of questions can result in missing some individuals who do not choose the trans identity but are also not cisgender.

The third measure focuses less on self-identity and more on perceived gender. This measure assesses how gender is perceived by others given that socially assigned gender can shape interactions and, arguably, could be more relevant than

self-identity for measuring some outcomes. These questions might focus separately on appearance and mannerisms, asking whether others would perceive them on a scale of very feminine to very masculine. These questions are, of course, most useful if paired with questions such as the two-step measure of gender identity in order to assess whether perceived gender poses greater negative outcomes for transgender or gender-nonconforming individuals. In addition, the focus is on current presentation and cannot account for how any prior different gender presentation contributed to present-day outcomes. Furthermore, the survey focus necessarily asks the respondent how they believe others perceive them; there is no way to ascertain if they are correct in their assumptions.

Finally, gender identity has been asked in questions that combine sexual orientation and identity. This can be done in a number of ways, some of which are problematic and ineffective by conflating two separate questions (sexual and gender identity) into a single question that could force a respondent to choose only one. Given that trans and gender-nonconforming people have varying sexual orientations, combining these into a single item could force individuals to choose their most salient identity and omit other information. The best-practice approach for combining these measures is essentially to treat each as a dichotomous response, where individuals can check yes to all that apply (bisexual, gay or lesbian, straight, and/or transgender). If an individual checks transgender, the Williams Institute report recommends a follow-up probe of male to female or female to male. One benefit of this question format is assessing whether individuals who check transgender also identify a sexual orientation; question testing has found that when sexual orientation is asked separately, transgender individuals often skip the question or write in transgender. By combining the question, responses to sexual orientation were prompted for some individuals. This question format also allows for a conflation of LGBTQ responses when desirable for the research question, such as when assessing employment discrimination or poverty levels that could result in a policy action targeted at aiding both sexual and gender minorities. This could be particularly strategic to conflate LGBTQ individuals given that laws protecting sexual minorities have passed in greater numbers than those narrowly focused on gender minorities. In addition, conflating groups within the LGBTQ umbrella could occur when sample size necessitates doing so because there are too few respondents in any one category to compare groups separately.

In assessing which of these four approaches to use, it is important to examine the research question or possible array of research questions that could result from the survey. Thus, while the two-step approach described initially is often touted as the best approach, when assessing effects of social perception on health outcomes (e.g., whether an individual is perceived as trans or as more or less masculine or feminine), it might be most beneficial to instead (or in addition) incorporate perception questions. This would better allow an examination as to whether perception and resulting treatment could be having an effect on trans individuals' health, as opposed to whether poor health outcomes are attributable to other factors (failure to seek medical care, hormone effects, etc.). In addition, some researchers have noted that questions that have primarily been tested with adults do not always translate to adolescents; furthermore, legal and policy limitations can curtail the collection of gender identity data for children. Thus, the question of measurement continues to complicate demographic research on trans individuals, contributing to the high volume of research examining best practices in measurement.

Demographic Characteristics

Using the available data sets containing varying measures of gender identity, researchers have attempted to answer questions such as the prevalence of trans populations; demographic characteristics such as race, age, sex, and geographic location; and outcome variables like income, employment, relationship status, and parenthood. Some of this information has been drawn from nonrepresentative surveys or qualitative interviews, given the primary focus on health outcomes in representative surveys (discussed in the next section).

In 2016, scholars affiliated with the Williams Institute compiled data from states' CDC BRFSS surveys to estimate that approximately 0.6% of the U.S. population, or about 1.4 million people,

identify as transgender. There was notable geographic variation in transgender identification, with approximately 0.3% in North Dakota compared to 0.8% in Hawaii. Falling in between these extremes were states such as Texas at 0.66%, Massachusetts at 0.57%, and Ohio at 0.45%. Although they found higher proportions of younger populations identifying as transgender, the variation was not as great as might be expected: approximately 0.7% of 18- to 24-year-olds identified as transgender, compared with 0.6% of 25- to 64-year-olds and 0.5% of 65+-year-olds. This suggests that, at least on survey responses, there is relative consistency in trans identity across cohorts. Of course, there could be much more variation in those who choose not to identify as trans on a survey.

In addition, as noted in the measurement section, there is variation in how trans individuals identify on surveys. For example, on the California Health Interview Survey (CHIS), 7% identified as male, 32% as female, 46% as transgender, and 15% as another gender identity. This is notable in that when demographers are estimating population size, they might undercount the trans population if the survey does not provide a means to identify that an individual who selects male or female is not cisgender. The inability to identify individuals who are male or female but not cisgender is particularly problematic if individuals who identify as male or female, rather than transgender or another gender identity, vary on important demographic outcomes. Their omission from the "transgender/nonbinary" sample would thus skew the demographic picture of this population. For example, the presence of those who identify as male but are not cis could result in lowering the income of the trans male population if those who choose to identify as male more readily pass and experience a resulting wage benefit.

Scholars have drawn on other survey data to analyze demographic characteristics of the trans population. According to a study using data from the 2018 General Social Survey (GSS) data, the only demographic characteristic on which trans and cis people differed was on the distribution of sexual orientations. This is likely attributable in part to the aforementioned greater likelihood of trans individuals to select the trans identity rather than to select a sexual orientation on surveys. Similarly, data from the CHIS have shown no statistically significant difference between trans and cis adults on demographic characteristics like education, citizenship, or residing in an urban or rural environment. But the CHIS data do mirror that from the GSS in showing notable variation in sexual orientation: While cis respondents overwhelmingly identified as heterosexual or straight at over 90%, there was greater variation for trans respondents, with the largest category as bisexual at 45%. In addition, trans respondents were far less likely to report being in a relationship, with three quarters indicating they were single compared to only 45% of cis respondents. The CHIS data also reflected almost two thirds of trans respondents were non-Hispanic white, compared to approximately 40% of cis respondents. This could reflect a real racial and ethnic difference between trans and cis individuals, or it could mean that individuals with greater privilege are more likely to identify as trans on a survey. With respect to income, there have been mixed findings regarding the trans population and poverty status, with some survey data reflecting a greater likelihood of falling below the poverty line for trans people and other survey data showing no difference between trans and cis populations.

Fear of discrimination could arise from negative experiences in the workplace, as well as additional settings. The Pew Research Center reported that about one in five LGBT individuals experience discrimination in the workplace. Some of these individuals go on to file charges of discrimination with the Equal Employment Opportunity Commission (EEOC) or state fair employment practice agencies. Between 2012 and 2016, the majority of gender identity charges were filed by those whose expressed gender identity is female, or male-to-female (MTF; 61%). This could suggest that perceived female gender expression is viewed more negatively than male gender expression, rendering this group more susceptible to discrimination and worse employment outcomes. Charges of discrimination covered an array of topics, with termination and harassment being the most common.

There are, however, some notable standouts unique to gender identity charges. Benefits-related charges were more common for gender identity charges than for those alleging discrimination based on sexual orientation, with about 7% of

gender identity charges involving benefits. This was driven by medical benefits charges, which are about 6% of all of the gender identity benefits charges. These claims were related to requests for coverage for surgery or medication related to gender identity. Finally, other charges unique to gender identity involved terms and conditions related to facilities and dress code. For example, approximately 12% of gender identity charges contained restroom or locker room issues, compared to only 1% of sexual orientation charges, and about 9% of gender identity charges dealt with dress code issues as compared to 2% for sexual orientation. These findings emphasize that gender-restrictive policies are relatively common issues in gender identity charges compared with sexual orientation charges. Furthermore, almost a third of trans respondents reported on the CHIS survey that their emotions (e.g., depression, anxiety) had interfered with their work performance within the past year compared with only 10% of cisgender respondents. These experiences with discrimination and navigating gender identity in the workplace shape labor demographic outcomes, including employment, occupation, and income.

These findings indicate that on many traditional demographic characteristics, trans and cis people are quite similar. On factors related to sexuality and relationships, however, there are notable differences that likely influence outcomes such as parenthood, experiences with discrimination, and health. In addition, differences in workplace discrimination can shape fundamental labor market outcomes for trans individuals. Finally, demographers should be cognizant when evaluating demographic characteristics that trans individuals might not choose to identify as trans (and might elect male or female) and might also abstain if they feel intimidated in doing so.

Health Outcomes

The addition of questions about trans identity to nationally representative surveys has been most common on public health surveys. As a result, we know more about trans and gender-nonconforming population health than we do about many other outcomes. With few exceptions, however, what we do know about health is limited to the broader focus of the particular health survey rather than what scholars might wish to ask specifically about trans individuals.

In terms of mental health, numerous studies have indicated that trans individuals experience a higher risk of suicide than the rest of the U.S. population. For adults, trans ideation in the past year is nearly 12 times higher than that of the general population, and it is nearly 18 times higher for suicide attempts. In a study drawing on the U.S. Transgender Survey (USTS), approximately 40% of adults had attempted suicide during their lifetime. Suicide attempts across one's lifetime were higher among adolescents and young adults, at about 42% for those aged between 18 and 44 years compared to only 28% for those aged 55 to 64 years and 18% for those over 65 years. Trans people reported similar risk factors for suicide as non-trans people (e.g., lower education, lower income) but also had unique risk factors. Several studies have found that harassment in public spaces, discrimination, lack of familial support, rejection from religious communities, and intimate partner violence also increased suicidal thoughts or attempts. Furthermore, some research has indicated that Black and Hispanic youth are more likely to report depression and less likely to seek care, placing them at greater risk for adverse health outcomes.

Research examining physical health outcomes has shown mixed results. For example, the CHIS data indicate no difference between trans and cis adults on health outcomes like asthma or diabetes or smoking, but trans people had a higher risk of HIV/AIDS and were more likely to report a physical or mental disability. With regard to HIV/AIDS, some studies have suggested a higher rate of infection due to a greater involvement in sex work or the use of social media to identify potential sexual partners. The most publicized health differential for transgender and nonbinary populations involves a higher rate of homicide, with Black male-to-female individuals being the most likely among trans individuals to die as the result of a hate crime.

Health outcomes for trans adults and adolescents are greatly influenced by their willingness to seek out medical care. In one study using the CHIS, trans adults were nearly three times more likely than cis adults to either delay or avoid seeking a prescription from a doctor. Health care utilization

varies across race and class for trans individuals, as well. Black and Hispanic trans and gender-nonconforming youth are more likely to report poor health outcomes but less likely to seek health care. In one study focused on transgender health in the South, white trans individuals reported positive health care experiences in general, but racial and ethnic minorities and those from lower social classes were more likely to report negative health care interactions. Health care has a high rate of discrimination toward trans individuals and a lack of informed health care providers, discouraging individuals from seeking the care they need. But these findings indicate that racial and ethnic minorities and low-income transgender individuals are less able to field potential discrimination or health care obstacles due to a relative lack of resources and privilege.

Some studies have, accordingly, examined factors that improve access to health care or reduce poor health care experiences. These measures are not just within the health care environment but can be shaped by broader laws and policies. For example, living in a state with protective policies—such as nondiscrimination laws, nondiscrimination protection in private health insurance policies, or the ability to change gender markers—has been found to be positively related to mental and physical health for trans individuals. Research reflecting the effects of these policies on the health outcomes of trans individuals is vital to making informed decisions about rules and policies.

Further Research

There has been increasing knowledge of gender variation at the population level, owing in part to the addition of questions to existing surveys, new surveys, and a growing interest in demographic outcomes for transgender and nonbinary populations. At the same time, it is clear there is a need for better survey questions and careful consideration of which measurement approach is best suited for particular demographic inquiry. Demographers must also exercise caution in interpreting data on gender given that surveys have demonstrated that trans people often identify in a binary fashion (i.e., male or female, rather than trans) that might obscure that they are not cisgender.

Data on traditional demographic characteristics are increasingly available, and much of it demonstrates little to no difference between trans and cis individuals. The differences that are appearing across surveys, however, suggest that more knowledge is needed about relationships, family, and sexual orientation for trans individuals. In addition, we continue to have little understanding of fundamental demographic questions, including migration or spatial distribution of transgender populations, fertility and household structure, labor market outcomes, or broader patterns of morbidity and mortality.

Developing research in these areas is essential to aid in developing best practices for health care, employment nondiscrimination, protection from violence inside and outside of relationships, and where resources should be concentrated geographically. A population perspective is an important component to answering these and other questions. Demographers should continue to turn an eye toward broadening our understanding of the transgender or nonbinary populations, as well as critically examining assumptions made about gender across demographic research.

Desistance

Desistance is a concept that has been borrowed from criminology and other psychiatric literature to describe the behavior of appearing to abandon an expressed transgender identity, particularly in children or adolescents. The term was first applied by a few researchers and then leveraged by various individuals or groups seeking to reduce or eliminate the incidence of trans identities and to curtail treatment options for young trans people. Some of the researchers who have used the term have since realized that doing so has led to stigmatization and psychological and physical harm for many young trans people, and they have acknowledged that more constructive and technically accurate terminology must be developed as scientists continue to study and learn about trans-identified children.

History of the Term

Desistance means to cease, as from an action; to stop or to abstain. In criminology, the term refers to the cessation of offending or other antisocial behavior. The term began appearing in child and adolescent psychiatric literature in the late 1980s in relation to emotional/behavioral problems such as oppositional defiant disorder (ODD) and problems associated with attention-deficit/hyperactivity disorder (ADHD), conditions in children that can cause adults to feel significantly "out of control" over the children in their care.

As applied to trans people, the concept of desistance was adopted in 2003 by an influential researcher for a presentation titled "Persistence and Desistance of Gender Identity Disorder in Children." This presentation was delivered at the Harry Benjamin International Gender Dysphoria Association's (HBIGDA, now known as the World Professional Association for Transgender Health, or WPATH) 2003 Scientific Symposium in Gent, Belgium. The term *persistence* had been a feature of the *DSM-III* diagnostic criteria for Gender Identity Disorder of Childhood (1980), but only

since 2003 has *desistance* as an oppositional term been applied to mean a child's or adolescent's relinquishment of a trans identity.

Beginning around 2013, when the publication of the American Psychiatric Association's fifth edition of the *Diagnostic and Statistical Manal of Mental Disorders* (*DSM-5*) redefined Gender Identity Disorder to Gender Dysphoria and seemed more validating of trans experience, frightened parents, nervous mental health providers, religious people who viewed trans people as violating the natural order, anti-trans feminists, and even a few people who had detransitioned began to develop arguments against social transition for trans children and medical treatment for trans adolescents. Citing an "80% desistance" axiom asserting that at least 80% of children ultimately reject a transgender identity, these groups campaigned to influence U.S. legislators at state and federal levels to draft laws and policies that would discourage social transition among prepubertal youth. By 2020, these efforts had escalated to legislative proposals in several U.S. states aimed at prohibiting social and medical transition for persons under 18 years of age and criminalizing health care providers, including therapists, social workers, and educators who deliver supportive care for trans youth. At the federal level, regulatory changes to the Affordable Care Act and to the interpretation of nondiscrimination provisions in the Civil Rights Act's Title VII (employment) and Title IX (education), as well as changes to military enlistment policies, were all weaponized against trans people during the Trump administration to deny them hard-won civil rights law and policy protections.

Problems With the Research on Desistance

The term *desistance,* used as a descriptor, was incorporated into reports of research done in the Netherlands, where some of the most progressive work with trans youth originated, including the introduction of puberty suppression. Published papers from a Dutch research team in 2011 and 2013 incorporated the concept of desistance as a phenomenon when they presented study data showing 16% to 27% of children whose parents brought them to clinics for gender dysphoria persisted in claiming a trans identity. Of the remaining 73% to 84%, the researchers reported they assumed that these children desisted from their trans identities when, in fact, some were lost to follow-up, while others stopped participating in the program without giving a reason. This mischaracterization of the data was then represented in various summaries discussing childhood gender identity development as 80% (an average from the data) of children who explore gender identity desist from those explorations when, in fact, the only conclusion that can be drawn was that approximately 20% persisted during the timeframe of the study.

Around the same period in the United States, increasing numbers of trans youth articulating their experiences, along with a rise in institutional recognition of trans rights throughout society, contributed to anxiety among some parents and religious groups who were seeking to put a stop to the proliferation of trans identities and expressions. These groups found justification for their cause in the concept of desistance and used the Dutch research to support their claims that trans care should be curtailed and trans rights rescinded to spare the 80% of children who questioned their gender from being encouraged to socially or medically transition. These characterizations of researchers' work and trans care in general represented a gross exaggeration of both the research and trans experience.

To date, there has been no specific research on desistance as a phenomenon. When researchers say, for example, "Five years after their first visit to our clinic, 20% of the 100 people in our study persisted in expressing a gender identity different from their sex assigned at birth," that does not provide concrete evidence that 80% of the people desisted or permanently abandoned a previously claimed gender identity, although this is precisely what groups such as Alliance Defending Freedom (www.adflegal.org) claim when they draft legislation or litigation aiming to prevent trans-identified children and youth and their families from accessing, and their care providers from delivering, such care. Thus, by using a controversial term, researchers opened the door to oppositional positions even when the data did not support such a position. For example, numerous studies of trans adults who were not diagnosed with gender dysphoria until age 30 or later indicate that most of these individuals were aware of their gender dysphoria when they were

quite young. They did not have the language to express their feelings to the adults around them, or they intuitively knew they should not express these feelings, or they were expressly instructed that they should behave in certain ways that conformed to the social roles expected of their assigned sex at birth. It is reasonable to think that at least some of the studied children who were assumed to be "desisters" might reveal their trans identities at some later time in their lives when they were more ready or able to manage the perceived social complications that can accompany such an identity.

Some researchers who take the position that desistance is widespread tend to believe that identity formation that flouts social role norms is aberrant and should be avoided. But there is no scientific proof that "desisters"—at any given point in time—have permanently abandoned a trans identity, nor is there any way to predict that a person who has not heretofore expressed a trans identity will not choose to express a trans identity in the future.

Exploring the Policy Debate

The subject of trans-identified young people seeking gender-affirming treatment is controversial, and the concept of desistance has provided ammunition for those who oppose the existence of trans people. Opponents of trans rights and access to trans-affirming health care seek to eliminate trans people from the social landscape by advancing legislation that will prohibit trans people from changing the sex or gender marker on their birth certificate or other official documents. These opponents insist that all people use bathrooms that correspond to their assigned sex at birth, seek to ensure that the term *sex* in federal or state civil rights laws is not inclusive of "gender" or "gender identity" but refers only to biologically determined sex, and strive to eliminate institutional support for gender-affirmative health care for both children and adults through insurance policy exclusions and hospital rules. They also support parents' rights to refuse to respect their children's expressions of gender exploration by restricting the availability of information that does not frame trans identity as problematic and avoidable. The "80% desistance" axiom is a weapon in this armory because it appeals to parents' understandable fears about harms that might befall their children. This axiom poses the question, "Why should we condone treatments that will have to be undone when your child changes his or her mind, since 80% of all children will ultimately accept that they are the sex they were assigned at birth?" This axiom proposes that by discouraging social transition, parents are saving their children the pain and embarrassment of confessing their natal sex when they change their mind, since that is what they are most likely to do. Desistance advocates frame preadolescent gender-affirming treatment as "sterilization" and "mutilation" (when these elements distinctly are not part of the protocol), which serves to frighten parents. Desistance advocates also draw on religious beliefs such as "God doesn't make mistakes," "God made your body and it is your responsibility to care for it and live in it the way God intended," and "You can't go against God's design." Desistance advocates also draw on the popular doctrine "You can't change your chromosomes," despite scientific evidence that chromosomes are not the only factor in determining sex, and it is presently unknown whether chromosomes have any influence over gender identity or expression.

Resistance to the concept of desistance has come from trans people and clinicians who support and practice the affirmative care model, which allows for children to explore and experiment with a wide range of gender expressions with no enforced "opposite-sex" trajectory or investment in outcome for the children other than their health and social safety.

Evolution in Terminology

While the choice to employ desistance as the inverse of persistence may have seemed linguistically appealing or even logical in 2003, the term's association with undesirable behavior has clearly led to serious problems for trans people, both in clinics and in legislatures, and, for young trans people, even in their families, as parents react to their children's revelations about their gender questions. Dutch researchers Thomas Steensma and Peggy Cohen-Kettenis concur with critics that the use of these oppositional terms, *persistence* and *desistence,* promotes a false binary and have acknowledged that they need to find better language for exploring the various possible outcomes and the fluidity that children's futures might hold. Terminology that is less stigmatizing, less polarizing,

and more descriptive of the explorations and modulations of identity that all young people are capable of experiencing can make these processes much less threatening for both trans people and their families. Such descriptive refinements may also help to diffuse the religious objections and even could elevate the science as researchers continue to seek information about the development of gender-diverse children and adults.

Detransition

To "detransition" is to reverse a prior transition from one gender or sex to another, typically returning to one's sex assigned at birth. The topic is controversial within trans communities, and the fact that some people do detransition is often cited by parents and policymakers as a reason to forbid transition to anyone. This entry begins by describing the process of detransition from medical and social forms of transition. Next, the entry discusses the various reasons why some people choose to reverse a prior transition. The section that follows presents the challenges faced by individuals undergoing detransition, and the entry concludes with a discussion of the responses of social networks and health care organizations to a person's choice to detransition.

The Detransition Process

For detransition to occur, a transition must happen first. Transition itself is often a complex process involving hormone replacement therapy over the life span and often multiple surgical procedures conducted over 2 or more years, often costing tens of thousands of dollars. A social transition (one without medical treatment) can also be complex. Both social and medical transitions involve explaining oneself to other people in ways that are often embarrassing and may be emotionally or physically threatening because of others' opinions or beliefs about trans people.

Medical Transition

A medical transition involves ongoing hormone therapy and one or more complex surgical procedures

usually conducted over a period of years; virtually every aspect of one's life is affected. Transitioners often go through the process of changing their names, pronouns, and legal documents, including driver's licenses, diplomas, and birth certificates. They must also tell their family members, friends, employers, and coworkers about their transition, except in cases where the transitioning individual severs all ties and starts a completely new life, which is difficult to do in the current age of connectivity. Detransition would be a reversal of these processes.

Detransition From a Medical Transition

Detransition can involve a number of steps. Some people begin detransition by stopping cross-sex hormone use. If the gonads have been removed, the hormones of the natal sex will have to be prescribed by a physician because the body will not produce them. If the gonads have not been removed, it is possible that the body can resume production of the natal hormones, but the endocrine function should be monitored by a physician to ensure that sufficient hormones are present for good health. Some effects of cross-sex hormone use are not reversable, depending on the length of time the hormones have been in use.

If surgery has been performed, it is not possible to restore one's original body. If the gonads have been removed, functioning gonads of the natal sex cannot be re-created. Any silicone implants such as breasts in trans women or testicles in trans men can be removed by a surgeon. A surgeon would be able to implant breasts for a trans man who was returning to living as a woman or to implant testicular prostheses for a trans woman who was returning to living as a man. A man who had had his penis removed and female external genitalia created could have a penis created through phalloplasty surgery (a complex medical process). A woman who had had phalloplasty in an initial transition could have the phallus removed, and depending on the original phalloplasty technique, some or most of the original female external genitalia may remain or may have to be reconstructed, although the clitoris may be lost. A woman who had had a metoidioplasty would likely retain a larger clitoris, although reduction surgeries may be attempted, which may damage sensation. It is necessary to have a surgeon assess an individual's situation to determine what modifications are possible or feasible to attempt and what are the likely outcomes.

Detransition From a Social Transition

Individuals who have undertaken a medical transition and choose to detransition will have to undergo a social transition as well. Individuals who have undertaken a social transition only (one without medical intervention) and who choose to detransition will have to effectively repeat the process by declaring their new name and pronoun, if necessary; changing all legal and other relevant documents (such as bank accounts, credit cards, commercial accounts, etc.); and informing all family, friends, employer, coworkers, and so on to advise them of any changes that might affect them.

It is possible for some individuals to undertake these processes without discussing them with anyone, depending on their circumstances.

Why Detransition Happens

Detransition occurs when a person comes to regret the previous transition. Feelings of regret can be motivated by many factors in an individual's life. A detransition may be the result of regret, pain, frustration, or other personal reasons that compel the individual to act. It may stem from the person's desire to alleviate something physically or emotionally painful, or it may arise from a choice to live in a way that they feel is better for them. According to empirical research, regrets are most likely to occur when an individual experiences a lack of social support following their transition or poor surgical outcomes.

It is important to note that not everyone who experiences some level of regret about a transition will actually detransition in response to such feelings. Rates of regret and rates of detransition, and even the occurrence of retransition, are not correlated and very much depend on individual circumstances.

The incidence of detransition is thought to be very low. According to the available research published in English, the regret rate following transition ranges from 0.3% to 3.8%. As a comparison, the regret rate documented in English-language research studies for patients who undergo total knee replacement (a much more common procedure than gender-affirming surgical treatment) stands at 20%, while an estimated 33% still experience knee pain following this surgery.

Detransition as Personal Evolution

It is possible for a person to detransition after their life circumstances change in ways that make them feel better able to accept their sex assigned at birth and its associated social role. In some cases, people who reach this kind of conclusion about themselves feel that their therapist did not do enough to help them find alternative approaches for managing their gender dysphoria or that their surgeons either did not do enough to help them understand what the consequences of the procedures would be or did not deliver the surgical results the patient expected.

Detransition for Medical Reasons

Some people may detransition due to a medical condition or a surgical failure. Some people's bodies have negative reactions to hormonal treatment, and some may feel that without hormones to support their gender expression, they cannot function successfully in their affirmed gender, so they may choose to detransition. Medical reasons for curtailing the use of estrogens in trans women may include estrogen-sensitive cancer, thromboembolic disease, or uncontrolled significant mental health issues. Medical reasons for curtailing the use of testosterone in trans men may include development of polycythemia (excessive red blood cells), extreme mood swings, extremely high blood pressure, and other cardiovascular risks. It is recommended that individuals considering using or discontinuing hormones consult a physician before starting or stopping hormone administration.

Detransition for Other Sociopsychological or Political Reasons

Some individuals are influenced by religion or political doctrine to renounce a prior transition. Younger transitioners who have not yet "found themselves" and who may be more susceptible to external influences are thought to be particularly subject to pressure to detransition for social acceptance, but people of any age may experience this. Discovering an affinity for the transgender exclusionary radical feminist (TERF) branch of radical feminism or experiencing a strong religious conversion, family pressures, or even a new love affair with someone who encourages detransition can influence a person to reconsider their previous thoughts, beliefs, or actions. A detransition also can be partial or temporary.

The purpose of counseling as recommended by the WPATH Standards of Care prior to transition is to help the individual be certain that their motivations for undergoing a medical transition are clear and rational and that they have the information needed to make fully informed decisions about their care, including the potential for detransition and the consequences for their body as well as their social context.

Detransition Challenges

Those who detransition may face challenging responses from several different camps: those who supported the initial transition and those who did not. Those who had originally supported the transition may feel uncomfortable with the decision to detransition and be unable to support that new decision. Those who did not support the initial transition may feel "vindicated" in their original lack of support and express an "I told you so" attitude in a way that communicates lack of support for the individual themselves, not just their actions.

Social Support Network Response

Many detransitioners note that their trans communities are not supportive of their decisions to detransition. Trans people often feel that detransitioners invalidate them and that detransitioners are contributing—wittingly or unwittingly—to efforts to remove trans people's access to social, legal, and medical transition. As a result, trans people and their allies may treat a detransitioner as a threat to their own social acceptance.

Conversely, groups like the Detransition Advocacy Network in the United Kingdom, evangelical Christian anti-LGBT campaigners in the United States, and TERFs everywhere claim that many clinicians who assist people who are questioning gender are forcing everyone down the same trans path (i.e., toward medical transition) without proper diagnoses or offering sufficient exploration to assist people in finding alternative ways to deal with gender issues.

Both of these positions create friction, harm, and antagonism.

The Politics of Detransition

The existence of detransition has been regarded as an undesirable outcome of a transition, and some anti-trans advocates regard even the possibility of detransition as a reason to prohibit a transition in the first place. In this regard, detransition functions much like the concept of desistance, which gives impetus to positions opposing access to transition for anyone. One rationale is expressed thusly: If there is a chance one would change their mind, then the transition is wrong in the first place, and therefore transition itself should be forbidden. This argument completely discounts the medical necessity of treatment for gender dysphoria as well as individual autonomy, and it indicates little to no empathy for the individual struggling with gender who should be allowed to make their own informed decisions at any time in their life, including decisions that involve weighing new information and coming to a different conclusion than one had reached previously.

Health Care Coverage

In the United States, many health insurance policies, if they covered transition-related health care expenses at all, have contained exclusions for detransition or reversals of transition-related medical procedures. This reflects a belief that if a trans person is to be taken seriously, then they should only assert the truth about themselves once, and if they were wrong, then they should have to live with their mistake. This rationale also discounts the medical necessity of treatment for gender dysphoria and supports an unrealistic approach to the circumstances facing trans and gender-diverse people.

Diagnostic and Statistical Manual

See DSM.

Dillon, Michael

Dr. Laurence Michael Dillon (1915–1962) was an ordained Tibetan Buddhist monk (*getsul*), a

surgeon in the British Merchant Navy, and the first man assigned female at birth to transition with hormones, top surgery, and a phalloplasty. Dillon, who was also known by his Theravadan and Tibetan names, Sramanera/Lobzang Jivaka, wrote the first text that advocated for clinicians to allow trans people to medically transition, *Self: A Study in Ethics and Endocrinology* (1946). Dillon's life and work are significant to the field of trans studies not only for his historically significant medical and social transition and his writings on the subject but also for his standing as a transnational religious figure. Dillon published prolifically on Buddhist topics, and his memoir *Out of the Ordinary: A Life of Gender and Spiritual Transitions* (2016) was heavily influenced by Buddhist concepts. This entry traces Dillon's life and work, conveying the significance of his complex positionality to the emergence of a medical and legal trans subjectivity, legacies of British imperialism, and the role of religion in trans identity.

Early Life and Transition

Born in Ladbroke Grove in London, England, in 1915, Michael Dillon was assigned female at birth and, along with his older brother Robert (Bobby), was raised by his maiden aunts. The Dillon family held a patrilineal aristocratic title, the baronetcy of Lismullen, and after his father Robert Dillon passed away when Michael was 10, Bobby became the new heir. During his formative years, Dillon also struck up a lifelong friendship with the town vicar, who encouraged him to pursue theology at Oxford, which he did initially but later switched to classics.

Dillon's college years were marked by increasing uneasiness with his gender and sexuality. Rowing on the women's team at St. Anne's College, Dillon managed to change the dress policy to allow for the crew to wear pants, but he refused to respond to friends who thought he was "probably homosexual." Following his time at Oxford, Dillon went to work as an auto mechanic in the town of Bristol and, in 1939, began taking testosterone tablets, which he obtained from a local psychiatrist to alleviate his gender discomfort.

Self, Surgery, and Surgeon

Dillon registered as male after undergoing top surgery from a sympathetic plastic surgeon in 1942. During this time, he also began studying at Trinity College, Dublin, to become a surgeon himself and wrote *Self: A Study in Ethics and Endocrinology*, the first text to advocate for the medical community to allow for people to transition. *Self* reflects themes that would return in Dillon's later writing: urging society to accept trans people, while not disclosing autobiographical details of his own transition and gender history. The 1946 text also argued for the innate naturalness of transsexuality and homosexuality, making it one of the first works to do so. While he was a medical student, Dillon completed his own medical transition, obtaining a phalloplasty from Harold Gillies in London, which made him the first man assigned female at birth to undergo the procedure. Gillies had developed the "suitcase handle" pedicle flap technique that he used on Dillon for male veterans with disfigured genitals from World War I and II injuries.

Dillon had an unrequited romance with race-car driver and World War II fighter pilot Roberta Cowell, who had read *Self* and was eager to meet its author. Dillon connected Cowell to Gillies and aided in her transition from male to female. Cowell does not appear in Dillon's memoir *Out of the Ordinary,* which may be due to her refusal to accept his marriage proposal in 1951. After graduating from medical school that same year, Dillon became a surgeon in the British Merchant Navy and began extensively studying esoteric theosophy.

Buddhist Ordination and *Out of the Ordinary*

The last decade of Dillon's life reflects both his increased discontentment with the values of European capitalism and materialism and his turn to Buddhism from esoteric philosophy. These changes are reflected in his prolific writings, including his self-published *Poems of Truth* (1957), which explores the theosophical themes of self, karma, and not-self. Dillon was heavily influenced by the works of George Ivanovich Gurdjieff, Pyotr Ouspensky, and especially Cyril Hoskin, who became a father-like spiritual figure for Dillon.

Dillon's gender history was discovered in 1958, because his name was still listed as his birth name in a peerage guide. The news was seen as

scandalous, and reporters from several sensationalist newspapers and magazines descended on the ship where Dillon was the surgeon. Heeding the advice of Hoskin, Dillon sought to avoid the publicity by leaving the Merchant Navy in Bombay and entering a Buddhist monastery to study meditation. But fearing that his gender history would become public in India, Dillon decided to come out to Urgyen Sangharakshita, the head of the monastery, who attempted to use the information to block Dillon's ordination into Tibetan Buddhist monkhood. Renouncing his possessions and wealth, Dillon became a postulate monk and depended on the generosity of the rural Indian communities where he lived for food and shelter.

To provide for his livelihood, Dillon wrote pieces in British Buddhist journals and four books: a social commentary on the Buddhist scriptures, *A Critical Study of the Vinaya* (1960); the children's primer *Growing Up Into Buddhism* (1960); the loosely autobiographical *Imji Getsul: An English Buddhist in a Tibetan Monastery* (1962); and a hagiography, *The Life of Milarepa: Tibet's Great Yogi* (1962). The final book Dillon would complete, his memoir *Out of the Ordinary,* was not published until 54 years after his sudden death in Dalhousie, India, of unknown causes in 1962.

Discrimination

Discrimination is defined as the unjust mistreatment of a person or group of persons on the basis of perceived differences such as race, gender, sex, class, ability, and/or sexual orientation. This entry addresses the social, political, and legal domains of discrimination that trans people face in the United States. It also addresses the ways in which social, political, and legal discrimination are entangled. Further complicating the matter is the fact that trans people belong to many other relational classifications such as race. Racism and transphobia can often overlap. As a consequence, trans Black women and trans youth of color are disproportionately affected by discrimination. Thus, discrimination against trans people takes many forms, from the highest levels of representative government to everyday encounters in the public sphere.

Alienation and Social Belonging

Discrimination against trans people is based on a number of persistent social biases. These biases are based on assumptions about the linkages between biological and cultural norms governing sex, gender, and gender identity. These are in part due to the prominent role that the medical sciences have played in establishing the notion that sex and gender are complementary binaries, and male and female correspond to man and woman. This two-sex model is often used as "evidence" for institutional and individual convictions that biology is the body's destiny. In other words, the medical "norm" has long held that the sex assigned at birth should govern the gender and gender identity of any given individual into adulthood. Many activists call this set of beliefs cisnormativity (from *cisgender,* or non-trans). Transphobia is an outgrowth of cisnormative values that organize beliefs about the body. This often questioned and problematized view, in turn, has contributed to the persistence and pervasiveness of transphobia, which in turn has severe and negative effects on trans people themselves.

Transphobia, which can take the form of alienation and ostracism, contribute to shame on the part of trans people, which can have traumatic consequences. For example, bullied trans youth are

at elevated risk for suicide as compared with their cis peers. Trans of color communities feel the effects of this ostracism even more. Racism has had a profound impact on American history and continues to do so. Trans women of color are subject to disproportionately higher rates of sexual abuse, relational violence, and homicide. Many reports have indicated that nearly 30 Black trans women have been killed every year since 2016. Consider the following narrative as an example of how social discrimination alters perceptions of self-worth:

> A gender nonnormative teen lives in Albuquerque, NM. Attending high school and identifying as a boy, ze identifies with girls. Ze's best friend is a lesbian activist on campus. Ze's gender *as* a boy had rarely been raised in terms of identity talk. Ze wasn't aware of the activism around trans issues. Ze wears blouses, makeup, nail polish, glitter, and has a hairdo others insist is for girls. These practices lent themselves to a sense of reliable self-knowledge and a material aesthetic that enhanced well-being. But they also attracted violent retaliation. Ze was bullied in and out of class. In one dramatic scene ze had a free weight thrown at them during lunch in the quad—the weight missed by a few inches. Then there are the words like "faggot" and "he-she" that injured—but more as a result of signaling the threat of violence than the sting of the words themselves. Teachers rarely intervened and, at one point, even told the teen to leave the classroom because ze was dressed in a long gown. The gown was disruptive. Through all this the teen did not complain to their family. With few outlets ze decided to repress these desires about expression and used cutting, burning, and other forms of self-harm to establish a sense of durability.

The effects of this kind of stress in social life can threaten to disrupt a trans person's connection to the world. Discrimination in social (or everyday) life causes persistent distress. Support and acceptance are necessary antidotes to these effects. Local advocacy groups, school organizations, and proactive allies can help mitigate the harmful consequences of persistent social ostracism. Many trans people, for example, find solace and emotional support through online forums and groups. These near-instantaneous connections have dramatically altered how trans survivors of discriminatory trauma communicate and manage their feelings.

Representation in Politics

Political discrimination is defined in two ways. The first is structural: a long-term lack of material and adequate representation within local, state, and federal government. Lack of adequate representation can have sweeping effects for a group or population. For example, in 2016, North Carolina enacted a "bathroom bill" (HB2) that required trans people to use the restrooms and locker rooms in government buildings and schools on the basis of the gender marker on their birth certificates, rather than their gender identity. Nationwide pressure, including boycotts of the state by conventions, performers, and sporting events, led to this provision of the law being repealed in 2017. Adequate political representation can positively alter the public perception of transness, trans communities, and individual trans life. Justice and democratic freedoms, such as voting and representation, are among the founding principles of American political life.

The second form of political discrimination is the erasure of pivotal trans actors in the histories of political protest in lesbian, gay, and bisexual liberation struggles. Archival scholarship has shown that the 1966 Compton's Cafeteria Riot in San Francisco was one of the first documented instances where the political energies and frustrations of trans people led to protest. Stories of Compton's remain relatively silent compared with the importance given to the Stonewall Riots of 1969 in New York. Stonewall has long been considered the birthplace of the queer rights movement. Trans groups, however, have pointed out how mainstream narratives that celebrate Stonewall routinely leave out trans rioters from their stories. Puerto Rican and Venezuelan trans activist Sylvia Rivera and Black trans activist Marsha P. Johnson were both integral in uniting and sustaining the pushback against the police leading up to and after the riots. Their stories are only belatedly being recognized. Choices about

which narratives in political struggles are retold and which are not can have profound effects on the perceived inclusivity of any social justice movement. Lesbian, gay, and bisexual (LGB) interest groups and other advocacy firms (organized in the 1970s) took decades to finally include trans and queer issues by name (LGBTQ). Including the voices of trans activists in the narrative origins of LGBTQ protest continues to reaffirm the inclusivity that defines the missions of these organizations for social justice.

Equality Before the Law

Legal recognition of rights contributes to civic belonging, protection, and well-being. By extension, legal discrimination may manifest as an *absence* of explicit statutory or constitutional protections (civil rights) and thus a total failure to protect trans people's legal claims in civil and criminal trials. Or, it may manifest as the *presence* of explicit statutory impediments to civic personhood. These forms of discrimination obscure or totally eliminate trans people's eligibility as rights bearers. North Carolina's HB2, for example, effectively eliminated the right of trans women to use the women's bathroom. The qualifying condition was whether trans women could verify that they had "transitioned"by having gender-affirming bottom surgery (vaginoplasty) in order to change the gender marker on their birth certificates. Despite its brief existence, the law had a number of effects. It consolidated notions that had historically and loosely circulated around trans people as perverts, deviant, and/or psychologically ill people. The law was passed in large part because of the rhetorical strategies that played on the perceived vulnerability of women and children. The bitter irony of the debate is that trans women (as women) and trans youth were constituent parts of those groups lawmakers referenced. Debates relied on little to no empirical evidence indicating the prevalence of sexual assaults in public restrooms. Anecdotal data and references to "common sense" were part of the House debate. A lack of political representation and transphobic norms made the already vulnerable group of trans women more socially precarious. North Carolina was not alone in that movement: Fifteen other states began considering similar legislation after HB2's media coverage.

Economic Inequalities

Economic discrimination directly impedes a trans person's ability to find work and limits trans people's general class mobility in a free-market system. Many employers continue to be unwilling to hire someone they perceive as trans. Trans workers often continue to feel discrimination at the hands of their coworkers and the customers they serve. Employment practices affecting trans people may or may not be regulated by legal protections. Over the course of time, these norms of economic behavior affect certain distributions of life chances. When solidified to the point of affecting entire generations, these norms become structural, or built into a given system. Left unchecked, such discrimination has populational effects. Scholars have found that upward of 97% of trans people surveyed have experienced workplace bias as a result of their non-normative identities. Furthermore, over half of the respondents in some large national surveys disclosed that they were denied promotion or being hired outright. There are many examples of individuals being terminated upon informing superiors that they were about to medically transition. The termination often ends with long-term under- or unemployment. In turn, trans people often find themselves in the paradoxical condition of being unable to afford gender-affirming surgeries so as to appear (by standards explained previously as denoting passing) more hirable.

In the United States, legal protections for trans workers have historically varied from state to state. Title VII of the federal Civil Rights Act of 1964 prohibited sex discrimination. This provision has been construed by a number of appellate courts in recent years to include trans people, but most trans workers remained unprotected. This situation changed in 2020, when the Supreme Court ruled that Title VII applied to trans (as well as cis LGBQ) employees, thereby offering nationwide workplace protection to trans people.

Most popular discussions of employment continue to discount sex work, and court cases do not include sex work as a "valid" form of employment. Yet sex work may offer many economically precarious trans people—more often than not women—a

means of economic security—although trans women face higher risks because both in and outside of the economy of sex work, they are fetishized. Because sex work is criminalized in most parts of the nation, it remains a para-economy whose participants face higher levels of physical threat from their paying customers. Statistics on assault and abuse may go unreported for fear of arrest or reprisal from the mostly male clientele. Given the continued precarity of sex workers, the risks against one's life are continuously high.

Conclusion

Discrimination is not a permanent feature of human life. Official institutions such as legislatures are charged with the responsibility of representing their constituents. Under the banner of constitutional equality, advocacy groups continue to litigate on behalf of trans communities to ensure adequate representation and equal treatment under the law. Public discussion and dialogue have been on the rise to ensure a greater number of everyday people learn about trans communities. Trans advocates and activists continue their efforts to broaden protections for (and thereby tell the stories of) trans people who are currently facing the layered forms of discrimination in everyday American life.

Divorce, Psychological Issues

Divorce (or relationship dissolution) represents a discontinuous, unexpected, and often dramatic change for couples and the individuals involved. It can bring with it a number of different, and potentially conflicting, emotions, such as anger, guilt, sadness, and relief. Such feelings can be exacerbated for trans individuals, who may be simultaneously facing personal challenges related to their gender identity or who may face stigma and discrimination from partners, legal systems, and mental health providers who would otherwise serve as a support for couples experiencing relationship distress or dissolution. Trans individuals may experience relationship dissolution at many points in their relationships. Their dissolution may also occur at various points during their own coming-out and transition process. Thus, experiences of divorce or relationship dissolution may vary widely for transgender individuals. This entry provides an overview of some of the psychological issues trans individuals may experience as a result of divorce or relationship dissolution. It also addresses some of the structural or external factors, such as legal concerns and access to mental health services, that can affect trans people's mental health during and following the end of a marriage or other significant partnership.

Common Psychological Issues Related to Divorce

Trans individuals, like all people, enter into romantic relationships in variety of ways and at various points in their lives. They may be in marriages or long-term partnerships, with someone of the same or another gender—or in one of a number of types of relationship configurations. Regarding relationship dissolution, some trans individuals divorce prior to coming out to their spouse, some divorce during the process of their transition, and some divorce after completing whatever transition process they choose to undergo. The cause of the

divorce may or may not be related to their gender identity or expression. Regardless of the reasons for divorce, trans individuals are likely to experience many of the same psychological affects as cis people who experience divorce.

A common effect of divorce is a change in overall life satisfaction, which research suggests is especially strong for women and also especially dramatic if the quality of the marriage was high (and, in turn, the revelation of the trans partner's gender identity led the cis partner to ask for a divorce). Alternatively, if the quality of the marriage was poor before the divorce (e.g., the cis spouse was rejecting of the trans partner based on gender identity or expression), there may be improved life satisfaction following divorce.

Like cis people, trans individuals may experience a loss of familial connections and social supports when their marriages end. Mutual friends may choose one partner over the other or may step back from the friendship in order to minimize their discomfort. In-laws are apt to cease (or at least greatly reduce) connection with the trans individual. Trans people's relationships with children can also become strained during and following a divorce or relationship dissolution. Adult children may create distance with their trans parent, either physically through lessened contact or emotionally by decreasing engagement during contact. Minor children may be kept from seeing their trans parent or discouraged from having a relationship with them by their other parent or family members. This rejection (actual or perceived) from their children may have a particularly negative impact on parents' mental health. Although not a great deal is known about the impact of a child's rejection, family rejection in general is associated with poorer mental health, and the rejection by a child can create boundary ambiguity (or confusion about the parent's role in the family system), which is likely to lead to poorer family functioning. This, in turn, can increase stress and decrease mental health.

This loss of social support from friends and family can cause isolation and may lead to depression. Loss of social support and relationships can be especially difficult for trans individuals who are unsure of some aspect of their gender identity or expression or who harbor internalized transphobia. They may feel that they do not have the right to be themselves or that nothing in their lives makes sense. Feeling that it is not okay to be themselves and that their lives are out of control can lead to worsening relationships with family and friends and further increase isolation. Moreover, holding negative views of trans people or what it means to be trans can lead trans individuals to view coming out to their spouse or families as selfish or lead them to take on all the blame for the marriage or relationship ending. Support groups and connection to others in the transgender community can help mitigate these effects but are unlikely to completely eliminate them.

Psychological Issues Unique to Trans Individuals in Divorce

As noted earlier, some trans individuals may experience divorce during their transition process, which may or may not be related to their transition. Regardless of the causes of divorce or relationship dissolution, it can have a deep psychological impact on the trans individual.

If divorce occurs as a result of one's transition (i.e., one's partner does not want to stay married during or beyond transition), this can lead to self-doubt, internalized transphobia, and decreased self-esteem on the part of the trans person. The trans individual may tell themselves that they were not good enough or that they are bad or selfish for transitioning or wanting to transition. These feelings of self-doubt and hurt can also lead some trans people to stop transitioning or try to detransition and live according to their "old gender" in order to try to maintain their relationship. This can increase feelings of shame and grief and lead to isolation from the transgender community and others who could serve as social supports during this time. As a result, the trans person may experience worsening mental health and diminished self-esteem.

Even if the relationship dissolves, the trans individual may still feel pressure to conform to their sex assigned at birth due to the value society places on being cis and the negative bias toward trans individuals. Because of these societal pressures, trans people may believe that in order to be wanted by someone else in the future, they need to present in gender-conforming ways. This can result in a variety of negative psychological effects, including increases in anxiety and depression, as well as low

self-esteem. It may also increase the risk of suicidality, as the trans person may feel that they are worthless, are bad, or will never be able to have a "normal" relationship or life.

Legal and Custody Issues in Divorce

Being involved in family court, whether for divorce or custody issues, can be a stressful and upsetting experience regardless of gender identity. However, trans people involved in the court system face some additional challenges. Perhaps most important is that judges—like members of society at large—are apt to be uninformed about trans people and hold negative biases and misunderstandings about them.

This negative bias can lead to custody issues and loss of contact with children, which can create additional psychological stress for the trans parent, above and beyond that of the divorce itself. Negative interactions with the court system may be particularly common for trans women, who are more likely to be subjected to minority stress and who may be viewed as "deviant men" by uninformed and biased judges. Because courts already tend to favor mothers in custody situations, trans women involved in custody cases may be particularly harmed by negative bias. If these women do lose access to their children (or have it severely limited), the reason given (whether directly or indirectly) is likely to be their gender identity. This can escalate feelings of shame and guilt regarding their identity and transition, as well as increase the likelihood of internalizing the negative messages they are receiving. All of this can increase the likelihood of developing or worsening depression. This stress may also be a trigger for suicidal ideation or suicide attempts.

It is important to note that there are some unique legal challenges for people who are nonbinary. Although nonbinary people have always existed, the legal system has been slow to catch up to this fact. As a result, the law is not written with them in mind, and lawyers may not know how to argue for their nonbinary clients' rights effectively, particularly if the client does not adhere to traditional parental labels, such as "mom" or "dad." Moreover, in a society and legal system that often seeks to categorize people into a binary, nonbinary people may experience more prejudice and be viewed by judges as less stable. This can make it less likely for them to be awarded custody of their children.

Access and Barriers to Mental Health Services

Despite the clear need for mental health services to help trans individuals navigate relationships and maintain their mental health throughout their transitions, many trans individuals have difficulty accessing competent care. They may have trouble finding a therapist who is versed in transgender issues, and they may even experience discrimination or bias from mental health professionals. Discrimination can take the form of counselors referring them out because the counselor is not comfortable or does not feel competent to work with transgender clients. Trans individuals may also experience biases from their therapist during sessions. This can happen in many ways, including microaggressions, such as misgendering or assumptions that transition must include hormones and/or surgery. Encountering bias, stigma, or lack of competency can lead trans individuals to withdraw from mental health services. This means that they will not be receiving appropriate services to assist them with the psychological issues related to divorce, leaving them at greater risk for mental health issues and suicidality. This may be even worse for individuals who live in areas where services are generally less available and attitudes towards trans individuals are generally more negative.

Trans clients who are seeking couples counseling during transition may encounter even more barriers. In particular, they may find that their therapist encourages (either actively or passively) them to dissolve their relationship. Many therapists are not appropriately educated to help a couple navigate gender transition together and can end up creating more damage to their relationship. For example, therapists may assume that the transition is the key problem in the relationship. They may incorrectly assume the sexuality of the couple based on heteronormative bias and suggest that one or both of the partners may no longer want to stay together due to perceived mismatch in sexual orientation. Couples seeking therapy should look for trans-affirmative couples therapists who are well versed in both couples therapy as well as transgender issues. A number of listservs and websites

maintain lists by region or state of gender-affirming therapists (e.g., www.thetransitionalmale.com, www.susans.org, www.wpath.org). There are also online forums and community groups that can help connect transgender individuals to supports and the larger community in order to help provide needed help for all trans individuals, including those who are experiencing relationship distress or relationship dissolution.

DIY

Do-it-yourself, often abbreviated as *DIY,* is a vernacular term used by many trans people to refer to practices of transition outside of the context of institutional and professional medicine. In the 21st century, in which the Internet hosts substantial forums and communities under this umbrella, the most commonly imagined trans DIY practice is the self-administration of hormone replacement therapy (HRT) with medications obtained without a doctor's prescription. This kind of trans DIY is subject to varying degrees of legality, depending on the location. However, the concept of DIY can be extended to encompass a wide repertoire of knowledge and practice by which trans people, either individually or in community and collectives, create access to, distribute, and make use of methods to affirm gender, whether or not these involve medical technologies. While the expert status of medicine typically casts DIY as dangerous or a tragic mistake born of a precarious life, it could be objected that the vast majority of trans people around the world today do not have access to safe, competent, and affordable health care. Although the history of trans medicalization might appear to imply that DIY transition is a series of amateur attempts to re-create clinical practices and scientific bodies of knowledge, a historical account of trans people's experimental and systematic practices to affirm gender and transform their bodies would question the priority of medical over DIY expertise. Rather than a derivative form, DIY is likely the most widespread form of transition in the world.

The Rise of DIY

The broader concept and the specific phrase "DIY" are both 20th-century U.S. inventions. Referring to the realms of "popular science" or at-home mechanics, as well as furniture assembly and home décor, DIY came into widespread usage in the context of post–World War II consumer culture. White, middle-class, suburban ideals of conspicuous consumption and enterprising individualism in a technoscientific era of manufacturing, technology, and domestic luxury popularized do-it-yourself kits, magazines, clubs, and societies for all sorts of projects that might be completed in one's garage, home, or backyard. By the 1950s, the term also began to take on a second meaning as the amateur practice of a craft, science, or other professional technique by a nonspecialist, or layperson.

The 1950s, not coincidentally, was also the decade that witnessed the emergence of the scientific and medical field of transsexuality, a new medical model that reclassified trans life by subjecting it to diagnosis and that produced the contemporary meaning of the word *transition:* the social, hormonal, surgical, and legal practices that trans people make use of in order to affirm their gender identities. While there were many vernacular traditions of what might be called transition prior to this decade, the social and medical senses of transition "from one sex to another" began to carry their contemporary meaning in a much more widespread way through the new field of transsexuality.

The coincidence of the popularization of DIY science and home projects with the worldwide celebrity of the U.S. trans woman Christine Jorgensen, whose story of traveling to Denmark for gender-affirming surgery broke in 1952, is illustrative of the twinned Cold War American projects of scientism and individualism. The country's new geopolitical, economic, and cultural hegemony, as well as its ideological contrast from the Soviet Union and other communist states, relied upon a vision of a new scientific malleability to the American body in the atomic age, one for which the idea of transsexuality was well suited.

While a few rare trans people like Jorgensen became visible through the narrow parameters of a medical model that celebrated the spectacular scientific possibility of "changing sex," many trans people who did not match her life as told in media coverage pursued DIY forms of transition out of a variety of motivations. For many, if not most, of these trans people, the primary motivation was a complete lack of access to institutional medicine, or the real fear of being given a risky psychiatric diagnosis, being institutionalized, and being subject to dangerous corrective therapies. Until well into the 1970s in the United States, for instance, it was practically impossible to obtain hormones or surgeries at legitimate medical clinics outside of a few places in major cities like San Francisco, New York City, and Chicago. The emergent university-based gender clinic model that began at the Johns Hopkins Hospital and Stanford University in the late 1960s imposed severe barriers on access, emphasizing the need for gender-normative comportment, heterosexuality, and the goal of erasing one's trans visibility by "passing." Many trans people who were able to find their way into these few existing clinics were rejected on those bases. Still more found that any other doctors willing to prescribe hormones often did so with little regard for medical ethics and patient safety and had no motivation other than profit. The exorbitant cost of transitioning through the route of institutional medicine made it an even more remote possibility for most trans women and men, despite its growing visibility in the postwar era.

DIY Hormones and Surgery

In this broader context, DIY formed a trans field of systematized lay knowledge and practice, as well as a repertoire of transition that transpired largely outside of the scrutiny of the state, the law, and medical expertise, although it has been subject to policing and attempted regulation. Modern trans DIY combined the two original meanings of the term from the 1950s. In the technological sense that was originally meant for popular mechanics and home furniture or construction projects, trans DIY took the sexed and gendered body as itself a kind of technology to be worked on or worked with. As such, DIY comprised any number of technologies for transitioning in daily life, including ways to dress, alter appearance, do makeup, bind the chest, modulate the voice, walk down the street unharassed, and participate in public and private social life. In the second sense of DIY as a layperson's participation in specialized practices, trans DIY also constituted a series of methods by which trans people acquired and practiced specifically medical techniques of transition, often illegally. Substantial underground markets for hormones formed in the late 1960s and early 1970s in the United States. In California, for instance, an underground network led primarily by poor trans women of color ensured a steady flow of estrogen purchased from Tijuana pharmacies in Mexico and smuggled by bus and car to major cities from San Diego to San Francisco, where the same women would resell and administer them. In the 1970s, a number of trans liberation groups attempted to set up DIY clinics that would serve as free alternatives to university gender clinics and might provide a holistic array of transition-related

care, including psychotherapy, support groups, and employment and welfare assistance. Some of these ventures even tried to hire their own surgeons. Rumors of DIY surgeries done under risky circumstances circulated through many trans communities in this era, although it is difficult to ascertain how common such practices actually were.

Connections to Trans Movements

DIY also played a role in some activist groups that emerged in the 1970s under the broader banner of trans liberation. This strand of trans politics largely affirmed the value of DIY, which stood in contrast to the ways that other, more reformist efforts to work *with* institutional science, medicine, the police, and the law generally held the goal of making DIY obsolete one day. While the reformist camp has received the most attention, trans liberationist demands for free health care and surgery on demand, along with local histories of DIY transition, can be seen as countermovements to depathologize and decriminalize transness and sex work, which many activists around the world pursued in the 1970s. As the 1980s witnessed the global emergence of the HIV/AIDS pandemic, many trans people participated in activism and DIY medical care work. Trans DIY knowledge contributed longstanding experience to AIDS activist critiques of state neglect and pharmaceutical profits from widespread death. Yet DIY was also the primary mode of innovative harm reduction models for safe sex and drug use, as well as underground or black market efforts to redistribute life-saving health care. Trans people were and remain disproportionately affected by HIV/AIDS because of transphobia, racism, poverty, and planned neglect.

In the 1990s, as the term *transgender* came into more widespread usage as an umbrella term for political recognition and organizing, the landscape of access to one hormone shifted significantly. The United States reclassified testosterone as a controlled substance in 1990, ostensibly because of concerns about organized sports and doping. Other countries and international bodies followed suit, significantly constricting the availability of this vital hormone for transmasculine people. In many cases, this resulted in criminalizing access to testosterone while simultaneously expanding the necessity of its DIY economy.

DIY in the 21st Century

In the 21st century, DIY remains central in most trans people's lives, although problems of access and legality operate quite differently in an age of global flows of capital and digital flows of information. The ongoing lack of insurance coverage for trans health care for those lucky enough to have health insurance in countries with private health care regimes, like the United States, continues to be an insurmountable barrier for many. In countries with public health care systems that are ostensibly trans inclusive, like the United Kingdom, severe wait times and outdated regimes of scrutiny and gatekeeping mean that services are similarly inaccessible. At the same time, many countries with state health care systems impose draconian caveats on medical care and legal recognition of transition, such as sterilization requirements in many parts of Europe. Despite the longstanding existence of worldwide standards of medical care and best practices, as well as a global economy in trans health tourism, there remains no identifiable access to transition-related care from institutional medicine in many places around the world. Or, in countries like Thailand, where the trans medical tourism industry caters to wealthy foreigners, transition-related care may remain out of reach for the local population, who are often employed to do care work and affective labor for Western clients. Each of these prevailing situations suggests that DIY would constitute by default the major market and practice for transition.

This overview, of course, still centers the United States and Europe as reference points. A more complex account of DIY would problematize both the umbrella concept of "trans" and the medical connotations of "transition" as artifacts of Western epistemologies. It is important to look to a wide array of different social, cultural, spiritual, medical, and technical practices around the world by which people affirm and express their gendered selves, including without the Western concept of "gender" altogether. At the same time, the heterogeneity and diversity of such practices and experiences cannot be flattened or rendered interchangeable, even if they all conceptually have DIY in common.

Perhaps the most historically significant shift in trans DIY, however, has come through the Internet.

The first generation of forums, listservs, and other online platforms for communication in the early 1990s was rapidly populated by trans people looking for social connection but also sharing embodied repertoires of knowledge and practice. The emergence of social media and the global diffusion of the Internet and smartphone connectivity in the 21st century have constituted another paradigm shift. Not only is the Internet a source of many detailed, comprehensive, and responsive forums for trans people "doing DIY," as the vernacular goes, but also hormones and other transition-related products can be sold and shipped around the world through the Internet, with varying degrees of legality, at a scale that eclipses anything that came before it.

Although DIY transition is a field of trans knowledge and practice that exists in relation to institutional science and medicine, it has not been recognized in its own right as a source of expert knowledge. Considering its persistence since the 1950s and its new reach in the digital age, DIY transition could play a more referential role in the field of trans studies and in the growing public interest in trans people and trans issues. Perhaps most significantly, trans DIY could be recognized by the medical profession as a robust and meaningful way that trans people have endeavored to survive and affirm their gender, often with great success and despite innumerable obstacles. In many instances, medical science has directly relied upon DIY knowledge to build its own protocols for transition, without giving credit to the many trans people who have shared their expertise with researchers and clinicians. Rather than an amateur derivative or a dangerous and unregulated last resort, trans DIY is more plausibly the single largest, most comprehensive, and insightful body of knowledge about sex and gender to emerge since the 20th century. To recognize it as such would substantially alter the power imbalance between sanctioned and unsanctioned knowledge and practice that the history of DIY catalogs.

Drag Kings

Drag is a form of entertainment that is usually performed by dressing up and lip synching and dancing to music in a show or contest. Drag kings are people—regardless of sex or gender identity—who perform masculinities in the context of a drag show or contest. While women have performed as men in various settings throughout history, drag kinging did not become common in the United States until the 1990s. In the 2020s, drag kinging is performed by cis women, trans men, nonbinary trans people, and sometimes cis men and trans women. The easiest way to describe drag kinging to people without cultural references is that drag kings are the opposite of drag queens; however, this description leaves a lot to be desired, because there are critical differences between the histories of drag kinging and drag queening. This entry discusses the history of drag kinging in the United States, who drag kings are and what they do, the importance of drag as a form of entertainment and as a challenge to the gender binary, and the benefits of drag kinging for performers.

A Brief History of Drag Kinging in the United States

Drag kinging history differs in its origins from the history of drag queening. The term *drag* comes from 19th-century British theater slang. Originally,

this term was used to describe cis men who performed in traditionally women's clothing. By the end of the 20th century, the term was also used to describe cis women who performed in traditionally men's clothing. However, before drag kings used this label, their predecessors were referred to as male impersonators. Due to the lack of research on drag kings and their relative invisibility in mainstream culture, it is difficult to precisely trace the beginnings of the term *drag king* and when this form of entertainment officially split from its predecessor, *male impersonator.*

In her 2018 book, *Just One of the Boys: Female-to-Male Cross-Dressing on the American Variety Stage,* Gillian Rodger explains that the first recognized male impersonator—a woman known for wearing men's clothing for the sake of performance—was Annie Hindle, who began performing in variety shows in the United States in 1868 after emigrating from England. In 1870, the term *male impersonator* began to be used when a second male impersonator, Ella Wesner, created competition for Hindle's act. Hindle's performances consisted of her dressing in costumes that mimicked realistic men's clothing and singing in a low voice. Hindle often interrupted the songs with funny monologues and jokes and developed a believable male character on stage. Hindle's and Wesner's popularity and notoriety on the variety circuits among both men and women opened the door for women to perform on stage as men in the United States, which was unheard of at the time. Before male impersonators, variety shows and comedy were both considered the domains of men, and a woman performer was seen as threatening to masculine privilege.

Jack Halberstam indicates in his 1998 book *Female Masculinity* that while male impersonators were the forerunners of drag kings, there are clear distinctions between these two types of performance. Male impersonation is theatrical, and the performer's goal is to appear as a realistic man. In contrast, drag kings do not necessarily seek to make audiences believe that they are men; rather, they often exaggerate or mock traditionally male behavior and mannerisms in order to expose the performativity of masculinities. However, both male impersonators and drag kings have been largely defined by the incongruence between their assigned sex and the gender they performed on stage. For instance, drag kings were still being characterized solely as female-bodied people performing masculinities in academic research at least until the late 2000s.

A number of drag kings claim to have started the usage of the term and/or to have been the first king to perform in the United States. Aside from when the term first began to be used, most scholars agree that drag kinging did not gain much attention in mainstream culture in the United States until the 1990s, given the marginalization of lesbians and the conflation of masculinity with men, especially white males. From at least the 1990s until the 2010s, drag kinging was the domain of lesbians and largely relegated to lesbian subcultures. One of the most prominent early drag kings was Mo B. Dick, who has been referred to as a founding father of modern-day drag kinging. Mo B. Dick started Club Casanova, which was billed as the world's first weekly drag king party, in New York City in 1996. When the show was shut down 2 years later, Mo B. Dick took the Men of Club Casanova on the road for the first drag king tour in the United States and Canada. In 1999, the first large-scale conference on kinging, the International Drag King Extravaganza (IDKE), was held in Columbus, Ohio, and the event continued annually until 2012. The first decade of IDKE is chronicled in the documentary *A Drag King Extravaganza.*

Since the 2010s, kinging has moved beyond lesbian spaces, as the sexual and gender identities of the performers have changed. Drag kings today are no longer primarily cis, lesbian women, as more and more binary and nonbinary kings have begun performing across the country. Drag, both kinging and queening, has also witnessed a growing number of cis people performing drag as the gender that aligns with the sex they were assigned at birth—that is, a cis man performing masculinity as a drag king (sometimes referred to as bio kings or faux kings) or a cis woman performing femininity as a drag queen (sometimes referred to as bio queens, faux queens, diva queens, or hyper queens).

The greater diversity of performers' sexual and gender identities today has led to changes in terminology and presentation. For instance, some trans men refer to their performances as male impersonation, rather than drag kinging, to avoid the historical association of kinging with cis lesbians. Another new aspect is that many performers

layer different gendered features to confuse the audience and demonstrate the performative nature of gender.

Who Are Drag Kings and What Do They Do?

Since the 1990s, most drag king performances and shows have taken place in queer bars and at Pride events. Performing as a king usually involves presenting one's body and attire as masculine, often exaggeratedly so, and lip syncing to songs. To get ready for a drag show, kings often spend weeks or months picking songs, preparing costumes, and practicing their performances. The initial step for getting ready for many kings is taping down, or binding, their breasts, if they have them. Some kings wear binders (tight undergarment used to flatten the chest), while others use elastic bandage rolls or even duct tape to bind. After taping down their breasts, some kings then "pack" their underwear. For kings without a penis, this is usually done by inserting stuffed socks, a dildo, or a specific packing device into their underwear. Then comes facial hair and makeup. For kings who do not have facial hair already, facial hair is usually an important piece to pulling off the illusion of drag. Some kings use makeup to draw on a mustache and/or beard, while others glue on actual hair. Some kings also use makeup on other parts of their faces and bodies to give themselves a more masculine appearance, such as darkening and extending their eyebrows and shadowing their chests and abs to look more muscular.

Next comes the costume. Drag king costumes vary widely and can be a contentious subject among performers. Some kings spend a lot of money and time preparing specific outfits for each performance; others wear traditionally masculine clothing that they had on hand. More experienced kings often complain about casually dressed kings, but less experienced kings are often using drag as an avenue to explore their masculinities, rather than to impress audiences. Many kings are more interested in "everyday" masculinities that would translate to their offstage identities. Especially for trans men and nonbinary people assigned female at birth, drag kinging serves as a resource to play with and explore gender in order to find what type of gender expression best fits them.

Once the king is taped, packed, made up, and dressed, it is time to go on stage for the performance. Most drag kings choose songs that are viewed as masculine and predominantly performed by men. Kings usually select upbeat, fast-paced songs for their performances, and as drag is a form of entertainment, they try to pick songs and attire that will please their audiences. Kings report that the attendees of shows are primarily women, and "sexier" songs bring better tips from audience members. Some kings model their drag persona after another man, usually a famous performer. Others base their drag king image on a more masculine version of themselves or on the more exuberant parts of their personality. Outfits may be designed to mimic the artist who originally sang the song or in the style of the type of music they are performing. Some kings' personas are the same regardless of song choices, while others alter their drag personas for each song.

In addition to performing gender on stage, kings usually also perform sexuality. Some kings perform as gay men, while others perform as heterosexual men, but the sexual identity of the performer does not necessarily match how they act on stage. Like the rest of their persona, the sexuality of the king could stay static across performances or may change depending on the song or role they are performing. Individuals interested in doing or learning about drag are now able to turn to tutorials on social media outlets like YouTube and to watch performances online and in films like *The Making of a King: A Drag King Documentary* and *Kings, Queens, and In-Betweens*.

Drag Kinging and Intersectionality

Drag queens tend to be more visible and well known in the drag community and in society more broadly than drag kings because of how women and men and their associated gender characteristics are valued differently. Whereas femininity is typically seen as a performance and often lends itself to humor, masculinity is taken seriously and viewed as something that just is—something that is embodied, yet not performed. So, while drag queens can play with femininity and make fun of it by taking it to extremes, drag kings are doing what Halberstam (1998, p. 259) calls "performing nonperformativity." Recognizing this difference,

more established drag kings often critique kings who are not extravagant and flamboyant, because masculinity in its "everyday" form is considered boring and nonperformative.

Another social distinction between kinging and queening is that kinging began in some places as an overt challenge to the gender binary system. This was particularly the case in a number of U.S. college communities, where lesbian feminists began to do kinging as a form of activism. But whether or not drag kings are more political and more critical of gender norms than drag queens, both types of performance can make audiences question the innateness of gender and help to disconnect gender performativity from specific types of bodies.

Along with difference in gendered performance, race is also a key intersectional factor within drag kinging. In "Mackdaddy, Superfly, Rapper: Gender, Race, and Masculinity in the Drag King Scene," Judith (Jack) Halberstam (1997) explains that kinging has different histories and meanings for white people than for people of color. Because white and Black lesbian communities developed separately in the United States, so too did the ways in which female masculinities took shape within these communities. Specifically, Halberstam suggests that Black female masculinities, and Black drag kings in particular, can be linked to the cross-dressing performances of women blues singers like Gladys Bentley in the early 1900s.

Another aspect that makes race a key intersectional characteristic for understanding drag is that, like femininities, masculinities of color are more visible and performative than white masculinities, which are assumed to be nonperformative. For example, people see rapping and dancing as performative, and these styles are linked to masculinities of color but not to white masculinities. In fact, many white kings initially found it challenging to make white masculinities engaging and exciting because they were seen as so normative. This situation has changed somewhat today, as more white kings are parodying masculinities in ways that may have been more difficult for them to do in the early 1990s.

Because lesbian subcultures were largely invisible in the broader U.S. society, lesbian communities developed relatively apart from each other, and this separation was still present in the 1990s when drag kinging began to become popular. As a result, kinging developed differently in different places, and some of these regional variations became quite pronounced. For example, Baker Rogers and Kimberly Kelly found that drag kings in the southeastern United States were more likely to say that they performed drag only for fun, and most kings did not identify with feminist goals. In contrast, kings in other regions of the country, such as on the West Coast, have stated that gender equality is a key reason why they perform drag. These regional variations point to the importance of studying drag in different communities and not just in big cities and not just on the East and West Coasts, where queer cultures, including drag king cultures, are thought to thrive. Drag also flourishes in small cities and rural areas, as well as in the Southeast, the Midwest, and other regions of the country where queer life is assumed to be absent or repressed.

The Social Importance of Drag

One important impact of drag kinging is its ability to expose how masculinities and gender performances more generally are social constructions with no basis in biology. That is, anyone can perform any gender. In line with this idea, scholars like Judith Butler and Esther Newton argue that drag is not a performance of some real gender, because no such gender exists. According to Butler, all gender is performance, and therefore, all gender is drag. There is nothing essential or natural about gender, and no gender can belong to a group (e.g., men, women, trans) based on the sex they were assigned at birth. Drag demonstrates the arbitrariness of gender as a category and challenges the assumed meanings of the concept.

Benefits of Drag Kinging for Performers

Drag has many benefits for those who perform. For one, drag is fun. A person gets on stage, lip syncs and dances, and entertains a group of people who are there to see them. Many of the more popular kings have booking agents who arrange shows and tours for them, and they receive performance fees in addition to tips from audience members. A few kings, such as Spikey Van Dykey and Gage Gatlyn, have become well known and established successful careers just doing drag. However, it is very rare for kings to earn a living on drag alone.

In addition to being fun and, for some, a source of income, drag is liberating and therapeutic for many kings. It is a way to understand gender and enact different gender expressions in a supportive environment, which is especially valuable when other sources of support are lacking. Trans drag kings in particular often use drag as a resource to examine their "felt" gender identity and begin to live comfortably in that identity. Drag has been especially important to trans individuals in the Southeast, because the political and religious conservatism of the area means that there are fewer trans-supportive resources available than in other regions of the United States.

Drag also serves as an outlet to escape the unreceptive environment that many binary and nonbinary trans people must navigate in their everyday lives. Trans people continue to face tremendous prejudice and discrimination in the United States, which can make them feel invisible, marginalized, and devalued. Performing to appreciative audiences can serve as a countermeasure, helping them to feel seen and admired. The communal nature of drag also provides kings with a support network, which can be especially important in more conservative areas of the country.

Societal Implications of Drag Kinging

Drag kinging is an amusing and enjoyable way for people to play and experiment with gender, but it also has serious implications in that it demonstrates that gender is a social construction. Male impersonation and drag kinging provide outlets to show the performativity of masculinities and that masculinities can exist outside of male bodies. These forms of entertainment allow people who do not identify as cis, heterosexual men to gain power and privilege. This could be a cis woman performing as a man in order to have her humor accepted in the 1860s; a cis, lesbian woman performing masculinities as a drag king in the lesbian bar culture in the 1990s and early 2000s; or, as is often the case today, a trans man doing drag in order to try on various types of masculinities that may not be accepted in his social circle in 2020. Whatever the circumstances, male impersonation and drag kinging permit those outside of the hegemonic position to claim the privileges of manhood, at least for the duration of the show. While many drag kings say they perform only for entertainment and fun, this does not negate the revolutionary potential of claiming and demonstrating that masculinities do not only belong to male-assigned individuals in our society.

Drag Performativity

Drag is a theatrical entertainment wherein a performer expresses readable identity attributes, most often those associated with gender. Drag performance is grounded in identity manipulation: Its primary purpose is to illustrate that identities such as gender are performative and achievable by various persons. Most often, drag is defined as a fictive, theatrical act that juxtaposes the actor's lived reality. Traditionally, this is articulated as the fundamental difference between the binary gender expressed onstage (i.e., masculinity or femininity) and the drag artist's offstage cisgender self (i.e., is "really" a woman or a man). This definition likely stems from drag's historicized connection to theatrical cross-gender casting. However, any person can perform drag, including people who do not identify as cisgender. In addition, drag performance is not limited to expressions of cismasculinity or cisfemininity. Drag actors often create gendered aesthetics that are fluid, fantastical, multitudinous, or unintelligible or that highlight relationships among gender, race, sexuality, and the body. Many believe that drag can be an effective tool for illustrating gender performativity, as well as visually representing queer culture.

Contested Definition

Some scholars and practitioners assert that the canonical definition of drag, while partially accurate, fails to fully encompass the scope of the genre. A common way of describing drag is to characterize how the actor's stage gender contrasts with their "real" gender and connected sex assignment. Under this definition, an artist who performs a recognizable version of femininity is a drag queen only if this theatrical look opposes his "real" cis male identity. Relatedly, drag kings are often described as women who replicate masculine stereotypes so to be perceived as "like men" onstage. Some suggest that this definitional framing is connected to a popular characterization of drag as the contemporary manifestation of cross-gender casting and male and female impersonation traditions. Drag is also interchangeably referred to as gender bending and crossdressing for these same reasons. While this definition accurately describes some forms of queening and kinging, it is controversial because it reduces drag to only those acts that produce binary gender, which are done only by people inhabiting the "opposing" gender identity.

In addition to emulating ideas that people are "normally" cis and "naturally" embody certain gender qualities, some also feel this definition excludes some very popular forms of drag. For example, trans women such as Peppermint work as feminine drag queens, and trans men like Lucky Johnson perform as drag kings. People assigned female at birth express a range of queer femininities through faux queening, bio queening, or female femme-ing acts. Some drag artists target oppressive gender norms by creating disjoined or

unintelligible identities or presenting gendered aesthetics in tandem with ideologically contradictory body parts, sexualities, or markers of race. For example, Conchita Wurst is a "bearded queen" who cultivates a highly feminine look with a full beard, and drag king Delicio Del Toro performs as a macho Mexican wrestler while exposing breasts. These types of acts, which are often explicitly referred to as drag and are integral to drag events, produce theatrical versions of identity and illustrate various ways identities can be done. In light of these examples, scholars such as Meredith Heller have argued that drag should be defined according to the intentions of its performers and the methods used to bend or otherwise disrupt dominant notions of identity.

Performance, Performative, Performativity

Drag is composed of a series of intent-laden actions that communicate particular messages to an audience. Drag actors cultivate their messages through meticulous and skilled engagement with makeup, body manipulation (e.g., binding, padding, tucking, packing), costuming, movement, voice, and dialogue. These elements are not intended to exemplify the artist's personal identity but rather to theatrically cultivate recognizable identity attributes. Because drag is a conscious and intentional act of identity manipulation, most scholars and practitioners agree that drag can effectively demonstrate how identities such as gender are performative or accomplished though readable aesthetics. Likewise, many also argue that drag illustrates how people not assigned these identities can do them as effectively as those for whom these identities are considered natural or normal. To encourage this interpretation, some drag performers use a reveal: an action such as a wig or clothing removal that visually marks divergence between the staged identity and the actor's offstage self. Whether or not a reveal is employed, drag is always a fictive, entertainment-based performance and therefore can never fully exemplify the actor's offstage or quotidian self. For this reason, scholars such as Marlon M. Bailey and drag artists such as Gia Gunn refer to drag as a profession—something people do—rather than a self-identity, or who people are.

Some propose that drag not only demonstrates how identities are performative but can also illustrate the theory of gender performativity. Judith Butler contends that gender is not a product of a person's nature but rather is embedded into a person's reality through institutionalization and participatory repetition. Performativity thus describes how social ideologies, when continually done through meaningful words and gestures, have real consequences and can make people into "who they are." Butler actually argues against drag's capacity to illustrate gender performativity because of how it is a fundamentally fictive performance genre; performativity characterizes a form of performative production that is neither fake nor temporary. Therefore, drag should never be used to describe the lives or identities of trans people. Relatedly, drag should not be used to contextualize "passing" actions, such as when women in Western history posed as men for the express purpose of obtaining "men's" jobs. Although these actions are performance based, they are not drag because they are primarily a method of blending with dominant realities, rather than using an entertainment forum to highlight how identities are performative.

Origin and History

There is no consensus about the origin or etymology of drag, but scholars often connect its contemporary practice to global histories of theatrical cross-gender casting. For example, early Kabuki performance was enacted by all-women troupes. After 1629 C.E., Kabuki became an exclusively men's practice, and male *onnagata* played woman parts. Ancient Greek play festivals barred women from public participation, so men performed all scripted characters. Male *dan* originally played women in Beijing opera because of gender prohibitions, but even after women were allowed to act, the practice continued on the basis of beliefs that men were better at developing idealized and artistic versions of femininity. In these historical contexts, cross-casting was an institutionalized means of upholding, rather than questioning or demonstrating, the flexibility of time- and place-specific gender ideologies.

A type of performance that became highly visible in the 19th and 20th centuries used cross-casting techniques to convey grotesque or titillating

characterizations. For instance, Ghanaian concert party, a form of traveling popular theater, included an upper-class snob character called "the lady," played for deprecating humor by a man. British pantomime and music hall performers like Dan Leno leaned on their masculine features to portray "dame" characters as ugly and overbearing. In U.S. and British burlesque, melodrama, and pantomime, women actors played youthful men like Peter Pan, ostensibly to increase verisimilitude. But, as exemplified by Adah Isaacs Menken's turn in *Mazeppa,* this convention was often a vehicle for publicly presenting women's bodies in tight, revealing costumes.

During this era, male and female impersonation emerged as a form of theatrical gender bending that was the result of neither social convention nor scripted cross-casting. Impersonators performed songs, dances, or comedy numbers, but their acts were primarily designed to showcase a detailed gender illusion that supposedly contrasted with their own natural selves. For instance, Annie Hindle became a variety star by performing her song-and-dance set as a boozy, upper-class playboy. Less commercial, public, or reputable settings fostered yet other kinds of gender-bending performance. Acts in these spaces were not always designed to emphasize rigid binaries between performed and lived gender, and they also tended to emphasize the relationship between gender and sexual desire. Superlative examples are blues and jazz performers such as Ma Rainey and Gladys Bentley, who sang and played instruments while wearing top hats, bow ties, and even full tuxedos. These women were not impersonating or playing men characters but rather performing in a masculine aesthetic that complemented and amplified their expressed sexual interest in women. While many formal conventions of drag practice reflect the theatrical structure of cross-casting and impersonation, it is also possible that contemporary drag emerged from these types of queer cultural entertainment practices.

Queer Culture

Some historical gender-bending performers had public same-sex relationships and sometimes lived in the gender they portrayed onstage, but the practice itself was seldom framed as sexually deviant or socially queer. In a Western context, this shifted when late 19th-century public discourse increasingly began tying people who crossed social or physical gender boundaries to same-sex sexual pathologies. For example, Richard von Krafft-Ebing's 1886 book *Pyschopathia Sexualis* makes reference to the possibility of "inversion" tendencies in actresses who perform in menswear. Turn-of-the-century commercial impersonators such as Vesta Tilley and Julian Eltinge took great pains to publicly identify themselves as having "normal" "opposite"-sex attractions.

At the same time, gender-bending performance was becoming an entertainment staple in queer community spaces such as gay bars. Scholars argue that these acts were alternately seen as queer forms of erotic gender play and campy methods of parodying heterosexual culture. Esther Newton's (1972) ethnography *Mother Camp: Female Impersonators in America* documents how, by the 1960s, conventionally feminine drag acts performed by men were perceived as a gay cultural product. As exemplified by the Jewel Box Revue's national traveling show, these acts could sometimes be performed widely and to heterogeneous audiences. Other acts were more tightly tailored to LGBTQIA+ communities and politics. For instance, in reaction to racist and colorist judging standards in the Miss All-America Camp Beauty Contest, Crystal LaBeija formed the House system, driving the development of ballroom into a space for queer Black and Latinx competitors. Stormé DeLarverie, the master of ceremonies for the Jewel Box Revue and rumored instigator of the Stonewall rebellion, performed in a butch aesthetic similar to Bentley's and Rainey's. It was not until the 1980s that the term *drag king* began to describe masculine acts produced by lesbians such as Diane Torr.

Contemporary drag is inextricably connected to the LGBTQIA+ community—although not all drag performers have same-sex desires or identify as queer. Nevertheless, drag is omnipresent at Pride events and, as exemplified by drag queen story hour, often used to introduce children to gender and sexual diversity. Drag scenes develop specific phrasings and vocabularies that are then generally circulated as queer community vernacular. As LGBTQIA+ people are more and more accepted by the dominant culture, drag has likewise mainstreamed, as evidenced by the critical and

commercial success of the television program *RuPaul's Drag Race*. Even in this highly commercialized format, drag actors incorporate fantasy, camp, showmanship, high art, eroticism, and cosplay into their staged expressions of identity. Many performers also use drag to communicate political messages about anti-LGBTQIA+ institutions and policies. Artists such as Vaginal Davis have incorporated drag into countercultural products such as punk and queercore music. The Boulet Brothers' *Dragula,* a show that features the subgenre of monster and horror drag, illustrates a range of artists that do drag in interesting and revolutionary ways.

Drag Queens

A drag queen is an actor (traditionally, although not always, a cis gay man) who performs theatrically as a woman in order to entertain and/or to parody, (re)produce, or critique binary gender norms. Aesthetically, most drag queens cultivate a hyperfeminine appearance by painting on heavily contoured makeup, tucking external genitalia, and donning wigs, high heels, and elaborately bedazzling costumes over bust and hip pads that create the illusion of an hourglass figure. In a typical act, a queen will dance and interact with audience members for tips while lip synching to a popular song. Queening emerged as a primarily Euro-American phenomenon in the late 19th century, and the practice spread across the globe in the late 20th and early 21st centuries, spurred by increasing access to social media and streaming video services. *Drag queen* in its contemporary usage differs from Western trans identities and from other culturally specific non-cis identities, like *hijra* (India), *khwaja sira* (Pakistan), *fa'afafine* (Samoa), *kathoey* (Thailand), and *travesti* (Brazil), inasmuch as it generally denotes a gender performance confined to the stage, rather than an everyday embodied sense of self. Nevertheless, recent scholarship and artistic practice have challenged the hard-and-fast distinction between drag and trans.

This entry reviews the history of drag from its 18th-century theatrical origins to its growth and flourishing in the United States from the 1880s through the Prohibition era and, later, the Stonewall Riots in New York City in 1969 and its subsequent emergence in contemporary mainstream media. The various subgenres of drag performance are described, together with their cultural scenes and settings. Next, the relationship between drag queens and gender identities is discussed. The entry concludes with a discussion of the critiques of queening on the basis of its depictions of femininity and the significance of its mainstreaming in the context of neoliberal consumerism.

Although there is no definitive account of its origins, the term *drag* is most commonly thought to have derived from mid-18th-century British theater, wherein the long gowns male actors wore when portraying female roles would drag on the floor. To put on drag thus came to signify crossdressing for the stage. Although men have been crossdressing for theatrical roles for millennia in various Anglo-European and Asian cultures, the "drag queen" is a distinctly modern invention. Whereas ancient Greek thespians and Japanese *onnagata* performed women's roles as part of a larger stage narrative, drag queens looked at crossdressing as both the defining convention and central purpose of the genre. Rather than telling a linear story, drag shows generally take the form of a competition or a series of unrelated individual

acts. In this sense, drag queens have something in common with turn-of-the-20th-century female impersonators of the music hall and vaudeville stages. But queening is distinguished from these predecessors by its explicit connection with homosexuality—an identity category that emerged contemporaneously with drag—and its pointed critique of the naturalness of gender.

History

Most scholarship has dated the birth of drag to the Prohibition-era United States and interwar Western Europe. New research, however, has uncovered evidence of a much earlier emergence in the 1880s via the figure of William Dorsey Swann, a formerly enslaved Black man believed to have coined the term *queen of drag*. Swann's Washington, D.C. drag parties were the precursor to the ball scene that emerged during the Harlem Renaissance. Perhaps more important, the juridical and journalistic response that these parties provoked produced drag as both a political performance and a marker of gender and sexual deviance. U.S. courts treated the parties analogously to brothels, echoing England's widely publicized Boulton and Park case a few years prior, in which two crossdressed men were arrested for solicitation and prosecuted under the statute for buggery, a catch-all for male homosexual sex acts, both public and private. Swann's biographer, Channing Gerard Joseph, notes that Swann is the first known person in the United States to defend queer people's right to gather via both explicit political action—an unsuccessful petition for pardon—and violent confrontation with law enforcement—a brawl following a police raid on one of his parties. Thus, Swann's practice established drag as an inherently political performance genre and as an identity category for assigned-male-at-birth (AMAB) people whose sexual proclivities or self-presentation defied traditional masculine norms.

Drag's illicit status persisted in the United States through the era of Prohibition (1920–1933), during which time organized crime–controlled speakeasies offered entertainment like drag and burlesque that flouted anti-crossdressing statutes. Drag queens of this era also performed at house parties, most commonly in Black neighborhoods, where the police were less concerned about protecting public morals. Around the same time, drag performance emerged in Black and Coloured South African townships and remained both an important symbol of defiant autonomy among its practitioners and a sign of their depravity to white government officials throughout the apartheid era. In the 1930s and 1940s, drag queens found a home on nightclub stages, giving rise to the phenomenon of drag bars in U.S. and Western European urban centers. It was during this time that "drag queen" became synonymous with male homosexuality. Whereas earlier crossdressers of stage and screen could carefully cultivate a straight masculine image for the press, such a curated persona was harder to maintain for performers who regularly interacted with their audiences in the space of the bars.

By the 1950s, drag had cemented its status as a LGBTQIA+ subcultural entertainment and, within a decade, as a political tactic too. Drag queens famously incited the 1969 Stonewall Riots in New York City that precipitated the gay liberation movement, and beginning in the early 1970s, *Tunten* ("trash queens") marched in gay rights demonstrations in West Berlin, prompting debate over respectability politics within West Germany's LGBTQIA+ community. Since then, drag queens across the world have been garnering celebrity status in their local queer communities.

Anthropologist Esther Newton famously referred to drag queens as heroes of gay male culture, both because they represent unashamed, loud, and defiant queerness in the face of violent suppression and because, for over a half century, queens have provided various forms of service and support to the LGBTQIA+ community. Since the mid-1960s, the International Court System, a nonprofit organization led by drag queens with chapters throughout the United States, Canada, and Mexico, has fundraised for and provided direct services to LGBTQIA+ community members, particularly the elderly, students, and houseless people. At the height of the U.S. AIDS crisis, free safer sex education targeted toward gay men was provided by the Sisters of Perpetual Indulgence, a satirical San Francisco–based order of drag queen nuns that has spread throughout North and South America, Europe, and Australia.

The turn of the millennium marked a new era in the evolution of drag. Although queens had long performed for pay in bars and clubs, the runaway

success of one drag queen in particular shifted the genre toward more distinctly consumerist ends. In 1993, RuPaul's surprise hit single "Supermodel (You Better Work)" brought drag to the widespread attention of straight, cis society and launched the artist's career in television, radio, and film. *RuPaul's Drag Race,* the competition reality show, premiered in 2009 and spawned numerous spinoffs, international versions, and a convention that attracts tens of thousands of fans annually. The show also produced the phenomenon of the celebrity drag queen, with top contestants winning modeling, television, and recording contracts and invitations to perform around the globe. The 2010s thus saw the transformation of drag queens from queer and trans community idols into mainstream commodities.

Genres and Scenes

Queening is not a uniform practice, but one nearly universal attribute of drag queen performance is its reliance on camp. Camp is an aesthetic and discursive mode that undercuts high art and heteronormative upper-class seriousness through bad taste, excess, and irony. Some scholars have identified usage versus disavowal of camp as the dividing line between drag queens and their performative kin, drag kings, who embrace an aesthetic of earnestness and restraint. The subgenres of drag queen performance are too many to name in a limited space, but this section will focus on several of the most recognizable categories.

House/Ball Scene

The house/ball scene originated in the United States in the 1920s as a response to racism, classism, homophobia, and transphobia. Drag houses are chosen families of predominantly Black and Latinx LGBTQIA+ people who adopt the surname of the house mother and/or father. Houses are complex kinship systems that provide care and safety to their members and, since the 1980s, have been especially critical sources of support and thriving for community members living with HIV/AIDS. Houses compete as a unit at drag balls, where contestants participate in a variety of categories, most of which involve walking a runway in costume. Judges assess contestants' skill at voguing (a dance form invented within the Harlem scene in the 1960s) and/or realness (the ability to pass as a straight, cis man or woman). In the early 1990s, the ball scene received international attention via Madonna's music video for "Vogue" and Jennie Livingston's documentary, *Paris Is Burning,* both of which were criticized by some feminists and queer and trans people of color as products of the white gaze and as exploitative of Black and Latinx performers, despite widespread praise in the mainstream press. More recently, the critically acclaimed television drama *Pose* has provided a glimpse into the New York City scene of the 1980s. Although house/ball culture remains a primarily U.S. phenomenon, in recent years, houses have formed in Japan, Taiwan, France, Mexico, Italy, Norway, and elsewhere.

Drag Bar Scene

Bar drag describes the category of performance that likely comes to mind when most people think of drag queens. Unlike members of the house/ball scene, bar queens generally operate as independent contractors, performing in pubs and nightclubs for tips and often a percentage of the bar's profits on the night. Most bar queens perform regularly at only one or two bars, particularly in smaller cities and rural areas that have a limited number of queer bars. In larger cities, queens may perform at a larger number of clubs and events, but the market for performance slots is also far more competitive.

In her landmark ethnography of U.S. drag queen culture in the 1960s, Esther Newton distinguished two types of bar queen: the street queens who lip synched to recorded music and the higher-status stage queens who did live singing and comedy acts. Over the half century that followed, this hierarchy flipped, with lip synch becoming the dominant performance medium. Although a quick, acid wit remains a hallmark of excellence in queening, live talk is now generally reserved for the brief interludes between acts at drag shows. Bar queens of the early 21st century are typically valued for the intensity of their performances, their dance skills, the outrageousness and quality of their costumes, and the artistry of their makeup, rather than their vocal talent.

Within the drag bar scene, there are several subsets of performance. Individual queens may move between these over the course of a career or even

within a single night. "Female impersonators" mimic a specific celebrity in physical appearance, voice, and mannerism. "Pageant queens" participate in contests for local, regional, national, and international titles that increase their prestige within the community and, in turn, make them more valuable commodities on the bar circuit. "Fish," a term derived from the supposed scent of the vagina, strive for verisimilitude—that is, to pass as a cis woman. Fish drag therefore tends to be subtler than most other types of queening, especially "high" or "glamour drag," which is hyperbolic in its performance of femininity. High queens often call upon garish makeup and enormous, complicated costumes to emphasize the performed quality of their drag. At times, high drag can overlap with "grotesque," which is described in the next section.

Genderfuck and Political Drag

Some scholars of drag have argued that all drag performance is political, given its constitutive assault on gender and sexual norms. As discussed above, the house/ball scene has inarguably always-already been political; in other drag scenes, claims to the inherent politicism of drag are more contested. While individual bar drag performances may be more or less overtly political, genderfuck artists always have politics out front.

Genderfuck is an umbrella term for gender performance that intentionally obscures or resists binary gender presentation and is a subgenre of both drag queen and drag king performance. The term is not exclusive to drag; indeed, some trans people use *genderfuck* to describe their everyday gender expression. Genderfuck artistry might be understood as the opposite of androgyny: Whereas the latter term typically connotes an indecipherable blend of masculine and feminine characteristics, the former is an intentionally unassimilable pastiche of them. Genderfuck performers thus frequently combine (the illusion of) traditionally masculine and feminine secondary sex traits in ways that highlight the clash of seemingly opposed gender signifiers, such as a drag queen with breasts and a beard. Two subsets of genderfuck are "skag drag," in which queens wear makeup and dresses but do not shave their facial hair or attempt to conceal a masculine body shape, and "grotesque"—popularized by the web series *Dragula*—in which performers reclaim the stigmatization of queerness by playing with bodily fluids or executing dangerous stunts.

Faux Queens

Faux queens—also called bio queens, although this term has received pushback within the community for implying a biological basis for gender—are cis women, usually queer femmes, who perform as drag queens. They adopt all the tropes of drag queen style, from heavily contoured makeup to padding to outrageous wigs and hairdos, and lip synch to popular songs for tips. This genre highlights the constructedness of gender by appropriating a gender expression (drag queen femininity) that is an appropriation of another gender expression (cis female femininity) that is itself variant across time and culture and constantly under revision. Faux queens have historically struggled for acceptance among drag queens, who argue that, by definition, drag requires the performer to cross gender. But the increasing outspokenness and popularity of both drag kings and trans queens since the turn of the millennium has helped to create more space for faux queens and other nontraditional drag performers.

Drag Queens and (Trans) Identities

Beginning in the 1950s and continuing into the 1990s, the term *drag queen* developed a rather nebulous relationship to gender and sexual identity. In the United States, following a period of increased gender and sexual freedom during the 1940s, when the exigencies of World War II demanded that middle-class white women work traditionally masculine jobs on the home front for the first time in history and soldiers confined to homosocial settings on the war front experimented with each other sexually, the 1950s saw a retrenchment of gender and sexual norms. The idealization of the implicitly white nuclear family with a male breadwinner and a female homemaker tightly lashed proper manhood and womanhood to heterosexuality. Within this context, "drag queen" became a repository for all things gender nonconforming and sexually rebellious.

Almost without exception, drag queens of this period were AMAB and identified as gay. Drag not

only provided a source of income for people whose flamboyance barred them from more traditional employment but also served as a vehicle for AMAB people to express femininity. In the decades before the word *transgender* gained currency, and in contradistinction to *transvestism,* which was closely aligned with heterosexuality through its most prominent spokesperson, Virginia Prince, *drag queen* was a term that applied equally to those who crossdressed exclusively for the stage, those who presented as women in everyday life, and those who engaged in both. Gay liberationists and cofounders of STAR House, Marsha P. Johnson and Sylvia Rivera, are perhaps the most famous examples of individuals who identified as drag queens, among other labels, and who later were claimed as (in Johnson's case) or came to identify as (in Rivera's) transgender.

Beginning in the early 1990s, three shifts led the category "drag queen" to be wrested from its denotation of gender nonconformity in everyday life. First, the term *transgender* began to circulate more broadly among the general public, offering the linguistic possibility of separating onstage and offstage gender performances. Second, the advent of RuPaul and a string of popular films featuring drag queens, most notably *To Wong Foo, Thanks for Everything! Julie Newmar* (1995), brought what had historically been a practice confined to the LGBTQIA+ community into the mainstream. These representations powerfully shaped the public perception that drag queens were effeminate gay men who performed theatrically as women. Finally, Judith Butler's pathbreaking book *Gender Trouble* (1990) framed drag queens as the archetype of gender performativity. For Butler, drag demonstrates that gender is appropriable and thus not real, in the sense of being inborn or originary. Her work also painted queening as a relatively socially acceptable form of gender subversion because the transgression is confined to the stage; by contrast, to present as trans in everyday life constitutes a much more substantial threat to the binary gender order. In later work, Butler softened the line drawn between drag and trans, and indeed, the increasingly vocal presence of trans-identified drag queens in local drag scenes and on the *RuPaul's Drag Race* circuit belies this hard-and-fast distinction.

Nevertheless, the relationship between drag and trans vis-à-vis identity remains fraught and culturally contingent. Some artists and theorists insist that "drag queen" describes a performance genre, not an identity category, while others claim that the link between drag and identity is more complicated. The latter argue that queening is at once a way to perform binary and nonbinary trans and male femininities and, for some performers, a step on the way to discovering one's trans identity. That is, although some performers come to drag having already come out as gay, femme, and/or trans, others come to identify as trans through the practice of performing in drag. While the general consensus in the United States is that *drag queen* should no longer be used synonymously with *transgender,* there remains some debate about whether it should be included within the trans umbrella, particularly given that the former's use as an identity category is racialized and seems to be most common among Black and Latinx people.

Critiques

Despite the fact that drag queens are generally lionized as celebrities within their local LGBTQIA+ communities, queening has been critiqued as a genre for what some see as its limited and limiting representation of femininity. Some critics argue that drag queens bolster the very stereotypes of women, femmes, and femininity that they purport to poke fun at. According to these critics, since drag queens often exaggerate feminine attributes to the point of absurdity for the sake of camp, drag appropriations of femininity run the risk of trivializing femininity. In other words, by treating femininity as a mere aesthetic or costume, and an over-the-top one at that, drag queens reinforce the notion that femininity is inherently superficial. Furthermore, since the kind of feminine gender expression performed in U.S. drag bars had been fairly monolithic until the 2000s (i.e., queens typically presented as hyperbolically feminine women rather than, say, nonbinary femmes), detractors accused drag queens of conflating femininity with womanhood and essentializing both. Often, such critiques also frame queening as an example of gay male misogyny.

These criticisms tend to target bar drag, rather than skag/grotesque or house/ball, and have been challenged primarily in two ways. The first is a philosophical argument: Femininity is not the sole property of women, and to assume that drag

queens are pantomiming womanhood when they perform femininity is in itself essentializing. The second is a historical argument: Defenders of the genre note that over the course of the 2010s, bar drag has become more diverse in its portrayal of femininities, with the lines between bar, grotesque, and genderfuck growing increasingly porous. The boundaries of what can be considered mainstream within the drag bar circuit have been pushed by internationally prominent and commercially successful queens like Sasha Velour, with her genderfluid, multimedia performances; Yvie Oddly, with her extraterrestrial, posthumanist costume design; and Conchita Wurst, a pop singer/songwriter who earns her nickname “The Bearded Lady.”

A final critique leveled against the genre is that white drag queens, particularly since the dawn of the *RuPaul’s Drag Race* era, have uncritically adopted the verbal and gestural lexicon of Black and Latinx house/ball performers. This includes both the circulation of slang like “henny,” “shade,” “read,” and “slay” and of movement vocabularies like voguing and waacking. These claims of cultural appropriation have largely gone without rejoinder. Since the mid-2010s, these claims have been subsumed by a larger critical dialogue about the mainstreaming of drag and its cooptation by neoliberal consumerist forces.

DSM

DSM is an abbreviation for the *Diagnostic and Statistical Manual of Mental Disorders* and is the classification system of mental disorders published by the American Psychiatric Association. The *DSM* contains descriptions and symptoms of disorders and criteria for diagnosing mental health disorders. The *DSM* is widely used by psychologists and psychiatrists in the United States and internationally to diagnose mental disorders and implement appropriate treatments. The *DSM* is also used by medical professionals, insurance companies, and the court system to define and diagnose mental disorders. The *DSM* is reviewed and revised periodically by researchers and clinicians on special task forces and work groups to integrate new knowledge based on the scientific literature. Since the first edition of the *DSM* in 1952 (*DSM-I*), there have been five major revisions, with the most

recent edition (*DSM-5*) being published in 2013. It is important to note that the *DSM* is influenced by, and influences, the World Health Organization's (WHO) *International Classification of Diseases and Health Related Problems* (*ICD*), and gender identity–related diagnoses are intertwined with the medical model of treating gender dysphoria. The *DSM* plays a significant role in the lives of trans people: It has previously defined the experience of being trans as a mental illness, which has had significant negative impacts by stigmatizing trans individuals. Currently, the fifth version of the *DSM* (*DSM-5*) includes the diagnosis of Gender Dysphoria, defined broadly as distress related to the incongruence between one's sex assigned at birth and current gender identity. Many medical providers require that an individual be diagnosed with gender dysphoria by a licensed mental health clinician in order to be eligible for gender-affirming surgeries or hormone treatment, and insurance companies often require this diagnosis to qualify for coverage of such procedures. This entry first describes the history of gender identity–related diagnoses within the *DSM* and then discusses current perspectives on the current gender identity–related diagnoses.

DSM-III—Transsexualism

The pathologizing of trans individuals by medical providers and psychiatrists began in the 19th century, with many psychiatrists writing about trans experiences as "pathological" well before the first edition of the *DSM* (*DSM-I*) in 1952. Additionally, trans experiences were often misunderstood as being related to sexual orientation and sexual desires. For example, in the 1892 influential text *Psychopathia Sexualis,* Richard von Krafft-Ebing described trans feminine gender expressions as sexual perversions and fetishes. The first appearance of symptom-based diagnoses related to trans experiences within the *DSM* occurred in 1980 with the publication of the *DSM-III;* this version contained the diagnoses Transsexualism, Gender Identity Disorder of Childhood (GIDC), and Atypical Gender Identity Disorder. These three diagnoses were classified as "psychosexual disorders" and relied on the essential feature of incongruence between anatomic sex and gender identity. The revised version of the *DSM-III* (*DSM-III-R*) included a few changes to the gender identity–related diagnoses. First, gender identity diagnoses were placed in a subclass of disorders first evident in infancy, childhood, or adolescence. Second, an additional diagnosis was included, termed *Gender Identity Disorder of Adolescence and Adulthood, Nontranssexual Type* (GIDAANT). GIDAANT was diagnosed among those who did not have a strong desire to receive gender-affirming medical interventions, whereas transsexualism was used for those who did desire such interventions. Interestingly, in the *DSM-III-R,* there were notable differences between the diagnostic criteria for "boys" and "girls" to receive GIDC. In addition to "persistent and intense distress about being a girl," children assigned female at birth (AFAB) were required to have a "*stated* desire to be a boy," whereas this criterion was not included for children assigned male at birth (AMAB), indicating to some that AMAB children had a "lower threshold" for being diagnosed with GIDC.

DSM-IV—Gender Identity Disorder

The main change in the *DSM-IV* (1994) was that GIDC and Transsexualism were collapsed into one overarching diagnosis called Gender Identity Disorder (GID) that included different criteria sets for children versus adolescents and adults, rather than having separate diagnoses. Additionally, the diagnosis GIDAANT was removed, owing to the lack of clarity of the differences between GIDAANT and transsexualism. Other notable changes between the *DSM-III-R* and *DSM-IV* were that criteria for GID focused on "cross-gender behavior" rather than "cross-gender" identity and added that disturbance in gender identity must cause clinically significant distress or impairment in social, occupational, or other important areas of functioning. One criticism of the criteria for GID was the use of gender binary language such as "boys" and "girls" and "opposite sex," which some argued excluded the experiences of nonbinary people who may have been distressed about their assigned sex but did not desire to be the "opposite sex." There were no revisions to the GID diagnoses from the *DSM-IV* to the *DSM-IV-TR,* an intermediary revision of the *DSM* between the *DSM-IV* and the *DSM-5,* and therefore, GID remained as a diagnosis until the publication of the *DSM-5* in 2013.

DSM-5

Gender Dysphoria

There were several changes to the gender identity–related diagnoses with the publication of the *DSM-5* in 2013, many of which were a result of trans activists who argued that the GID diagnosis legitimized stigma toward trans people. The changes made were decided on by the Workgroup on Sexual and Gender Identity Disorders, which consisted of a group of psychiatrists and trans health specialists. In an effort to destigmatize trans people while also retaining a clinical diagnosis to show "medical necessity" to enable access to insurance coverage for gender-affirming medical care, GID was changed to a less stigmatizing name of Gender Dysphoria (GD) and moved to its own section of the *DSM,* rather than being included with the paraphilias and sexual dysfunctions. One goal of the *DSM-5* was to diagnose the "distress" rather than the "identity" as the problem. The main diagnostic criterion for GD is having a "marked incongruence" between one's assigned gender and one's experienced/expressed gender and that this incongruence creates distress. The criteria must be met for at least 6 months. This time period was to be established on the basis of "clinical consensus," and the stated intention is to differentiate "transient" GD from "persistent" GD. Notably, in the *DSM-5,* there are separate criteria for GD in children versus GD in adolescents and adults, with the criteria for children being more stringent and including more behavioral criteria. For example, children must meet six of eight criteria to be diagnosed with GD, whereas adolescents and adults only need to meet two of six criteria. Examples of behavioral criteria include "a strong preference for toys, games, and activities stereotypically used or engaged in by the other gender" and "a strong preference for playmates of the other gender."

Transvestic Disorder

In addition to the gender identity–related disorders, the current version of the *DSM* (*DSM-5*) includes Transvestic Disorder among the paraphilic disorders. The disorder includes two main criteria: (1) experiences of recurrent, intense sexual arousal from fantasies, sexual urges, or behaviors from crossdressing for at least 6 months and (2) the fantasies, sexual urges, and behaviors are causing clinically significant distress or impairment in social, occupational, or other important areas of functioning. This diagnosis can be traced back to the first *DSM* in 1952 and was termed *Transvestic Fetishism,* a subcategory of Sexual Deviation classified under personality disorders. In the *DSM-III,* the diagnosis was moved to the paraphilias and was only diagnosed in heterosexual men. In the *DSM-5,* the diagnosis includes four specifiers: (1) with fetishism—the individual is also aroused by fabrics and materials; (2) with autogynephilia—when a man is sexually aroused by thoughts or images of himself as female; (3) in a controlled environment—the individual lives in an institution or controlled setting where crossdressing is not possible or is restricted; and (4) in full remission—there has been no impairment in functioning for 5 years. The term *autogynephilia* was coined in the 1980s by Ray Blanchard, who theorized that the motivation for gender-affirming medical interventions was related to either sexual orientation (e.g., trans women would desire medical intervention because of their attraction to men) or due to their own sexual arousal. Many in the trans community find the term *autogynephilia* deeply offensive and have criticized Blanchard's work for its lack of scientific validity.

Varying Perspectives of *DSM* Gender Identity–Related Diagnoses

Within trans communities, there are varying opinions about the usefulness of the diagnoses in the *DSM*. Some trans clients relate to the concept of gender dysphoria and, as with other mental health diagnoses, benefit from learning that their experience has a name and is experienced by others. Other trans community members do not relate to the concept and may resent needing to be diagnosed with a disorder in order to receive gender-affirming medical care. Many in the trans health community see the changes in the *DSM* diagnoses as steps forward in destigmatizing trans individuals by shifting the focus to treating distress rather than treating the individual's identity. Additionally, many believe that at diagnosis within the *DSM* is necessary in order to justify the medical necessity of gender-affirming medical interventions. Most insurance companies require proof of medical

necessity to provide coverage in order to differentiate procedures that are for cosmetic purposes versus health purposes.

Others argue that the very existence of gender dysphoria and transvestic disorder continues to perpetuate harm to trans communities. The continued requirement of needing a mental health diagnosis in order to receive gender-affirming medical care continues the gatekeeping practices that have existed since the inception of trans medicine in the 1960s. *Gatekeeping* refers to the requirements that trans people must meet in order to gain access to hormone therapy and gender-affirming surgeries. Currently, most medical facilities and health insurance companies require that trans individuals acquire one or more letters of support from a psychologist that state the client has a diagnosis of gender dysphoria. In the 1960s and 1970s, clinicians evaluated whether clients were "true transsexuals," defined as having cross-gender identification consistently expressed since childhood; no sexual arousal to crossdressing; the ability to successfully "pass" as their desired gender; and heterosexual interest based on their sex assigned at birth. In the 1980s through the 2000s, many clinicians followed guidelines published by the World Professional Association for Transgender Health's Standards of Care (WPATH's SOC), which stated that clinicians should evaluate the client's "readiness" for surgery by documenting that the client had had at least 12 months of "real-life experience" living as their expressed/desired gender and had required psychotherapy for varying amounts of time.

Since 2012, WPATH guidelines and many trans health experts have shifted toward an informed consent model in which the clinician, when writing letters of support, evaluates the client's ability to provide informed consent rather than the validity and stability of the client's trans identity. There is not a clear consensus among psychologists and psychiatrists on whether the letter requirement should remain; however, many trans health advocates believe the letter requirement takes away the power from trans individuals to make their own health care decisions and may be rooted in trans prejudice.

Last, many have critiqued the diagnoses of gender dysphoria and transvestic disorder because of these diagnoses' potential to perpetuate negative stereotypes about trans people, which may increase their risk of experiencing discrimination, harassment, and violence. Although the American Psychological Association and WPATH have made public statements that being trans is not itself a mental disorder and should not be viewed as pathological, others may still use the American Psychiatric Association's *DSM* diagnoses as justification for perpetuating these messages. A pathological view of trans identities may be used to justify "reparative therapies" that aim to prevent individuals from embracing a trans identity or transitioning. Such treatments have been shown to be ineffective and psychologically harmful. Some trans activist groups claim that transvestic disorder perpetuates the stereotype that being trans is related to a "sexual perversion" and that trans people are sexual predators. This specific negative stereotype has been said to fuel anti-trans legislation such as the "bathroom bills" banning trans people from using public restrooms that match their affirmed gender.

Elbe, Lili

Lili Ilse Evenes, known as Lili Elbe, was as an early recipient of gender-affirming surgery. Born in Vejle, Denmark, in 1882, Elbe was assigned male at birth and christened Einar Magnus Andreas Wegener. Under the name Einar Wegener, she established a solid career as a landscape painter. In 1930, Elbe successfully petitioned the Danish state for a change of name and gender. From 1930 to 1931, she undertook a series of surgeries in Germany, the last of which resulted in her untimely death. Her life story, *Fra Mand til Kvinde* [*Man Into Woman*], was posthumously published in Danish in 1931, with a German version appearing in 1932, an English one in 1933, and an abridged French serialization in 1934. This entry looks beyond the well-known narrative of *Man Into Woman* to examine how Elbe's own art aided her self-expression as a trans woman and also to consider why her experiences are remembered, whereas other men and women who sought gender-affirming surgery in Germany in the 1930s have almost faded from history.

Art and Affirmation

In 1902, Elbe began studying art at the Royal Danish Academy of Fine Arts in Copenhagen, where she met Gerda Gottlieb, who became her wife in 1904. Both artists had some success in Denmark, but in 1912 they left for Paris, the center of the European artistic avant-garde. Gerda Wegener was a figure painter and often used Elbe as her model. In her memoirs, *Mosaïques,* Hélène Allatini records that Elbe first posed for Gerda before the couple moved to France. One day an actor cancelled a sitting at the last moment and Elbe stepped in. That evening, she was baptized with champagne as "Lili." The anecdote reveals the strong association between art and self-fashioning, one that continues to resonate today in debates about trans cultural production and the politics of visibility. In his 2015 essay, "The Trans Woman as Model and Co-Creator," Tobias Raun argues that Gerda's many portraits of Elbe provided her with a crucial space for self-recognition and realization. The various guises in which Gerda portrayed her—companion, coquette, seductress, studio nude—form potentialities to be explored in the safe virtual space of canvas or paper.

Focusing solely on Gerda's artworks, however, risks ignoring ways in which Elbe's own landscapes and interiors sometimes enabled her to articulate her experiences as a trans woman living within a culture and society lacking an adequate or appropriate language for trans experience. Her 1916 self-portrait, *Fra et boudoir* [*Woman in Her Boudoir*], can be read as a determined affirmation of self that refuses a fetishizing or objectifying iconography. The painting does not directly portray Elbe, yet signs of recent dishabille—a shed slip and a pair of discarded elegant button-boots—imply her presence. We can be certain that the interior is Elbe's because in her account of first meeting Gerda and Lili in Paris in 1916 (the same year the

painting was made), Allatini remembers seeing two parakeets in their studio, and such birds are in *Fra et boudoir.* A 1917 photograph of the studio also includes furniture and fittings reproduced in the painting.

In *Fra et boudoir,* Elbe seems to simultaneously offer and withhold herself, fostering reflection regarding trans visibility and invisibility. She knew the violence of visual misrecognition and incomprehension firsthand, having been laughed at on a bus journey for her appearance. On another occasion, a photograph of her posing was torn up by a man who had found the model alluring, unaware it was Elbe. On discovering her identity, he felt “deceived” and attacked her image. In the context of such phobic responses, Elbe’s recourse to allusion rather than direct representation in *Fra et boudoir* can be read both as a guarded rejoinder to the hostility trans people were subject to in the early 20th century and to the iconographic limitations of her time.

Lost to History

Elbe is often wrongly identified as the first person to receive gender-affirming surgery. From 1930 to 1931, she agreed to at least four operations: an orchiectomy, the transplantation of an ovary, a penectomy, and a vaginoplasty. She may also have had a uterus transplant. Many of Elbe’s medical records were subsequently destroyed by the Nazis and by the Allied firebombing of Dresden. Despite this, Elbe’s experiences remain well known because of her bestselling life story. In the early 1930s, another relatively successful artist, the German painter Toni Ebel, was also undertaking gender-affirming surgery, yet she is rarely mentioned in histories of trans health care. Other contemporaries, such as Charlotte Charlaques and Dora “Dorchen” Richter, are also sidelined.

An intersectional approach helps to nuance our understanding of Elbe’s medical experiences. She came from a middle-class background; her father owned a small retail business. As an artist, she was bohemian but bourgeois, wealthy enough to pay for multiple surgeries in a short time span. Dora Richter, by contrast, came from a rural working-class family and had to take a job at the Institute for Sexual Research in Berlin to pay for her operations (as did the avowed socialist Ebel). All these women courageously submitted to experimental, painful surgeries. Elbe, however, had recourse to a social network and economic resources, which most of her contemporaries did not. In that sense, her ability to access and afford trans health care was atypical.

Afterimages

The surgical procedures Elbe undertook need to be understood as on a continuum with the artworks that affirmed her gender. Three of her surgeries were performed by the surgeon Kurt Warnekros, who she regarded as an artist. After her surgeries, she ceased painting but turned to literature as a creative outlet. While *Man Into Woman* uses multiple sources, Elbe clearly had significant input, reading and commenting on drafts. The glimmerings of a new career as a writer, however, were curtailed by her tragic death from surgical complications. In this century, Elbe’s life story inspired David Ebershoff’s popular 2000 novel *The Danish Girl,* which was adapted into a 2015 film that starred cis actor Eddie Redmayne as Elbe.

Elected Officials

Since at least the 1990s, openly trans people have sought, although rarely won, political office in the United States. In recent years, however, an increasing number of trans people have run for elected office and increasingly have been successful in doing so, both reflecting the growth in trans visibility and contributing to that growth. This entry focuses on trans elected officials and candidates for office in the United States and discusses the importance of political representation, different types of representation, notable firsts for U.S. trans candidates, and patterns in these elections thus far.

The Importance of Representation

Representation in governance is one of many potential ways to assess minority experiences in a given country. Elected officials craft laws and policies, and they can shape public opinion about many issues. If minority group members hold elected office, it is more likely that their interests will be protected or pursued in policy. In 1967, noted scholar Hanna Pitkin described symbolic, substantive, and descriptive forms of representation, which each help explain the importance of representation.

Symbolic representation occurs when an elected official, of any identity, does something that might be meaningful to a constituency, even if only superficially. For example, a heterosexual and cisgender official might attend an LGBTQIA+ Pride parade or propose naming a post office in honor of a Black or Latinx community member. Symbolic representation can also refer to intangible benefits or effects created by that elected official, such as the impact of being the first member of a minority group to be elected to office.

Substantive representation occurs when an official actually advocates for the material needs and concerns of a community, above and beyond symbolism. For example, an elected official could provide substantive representation for the LGBTQIA+ community by securing funding and support for a shelter for LGBTQIA+ homeless youth.

Descriptive representation occurs when elected officials share identities with their constituents, as is the focus of this entry. This is important because descriptive representation makes it more likely that both symbolic and substantive representation will occur. Research has shown that elected officials are far more likely to represent the interests of a group when they themselves are a member of that group and further that these efforts lead to important outcomes for their group. Descriptive representation can also be important in other ways. Having a member of a minority group in a legislature can influence the attitudes and behaviors of other legislators, and it can also improve the attitudes of the general public toward that minority group. In some cases, minority group members who live in districts where they are descriptively represented are more likely to be active and interested in politics themselves.

Importantly, descriptive representation can occur across geographic bounds of a district. In 2017, Danica Roem became the first openly trans person to serve in a state legislature. She was elected to a relatively small district in Virginia, but her election is widely referred to as a momentous turning point in trans political representation in the United States.

In sum, the presence of a minority group in the halls of government has the potential—although not necessarily the guarantee—to greatly influence laws and policies that affect that group, as well as public opinion about that group. As a result, many people use representation in government as one measure of the sociopolitical progress of a minority group.

Historic U.S. Firsts

When studying historic or first achievements of LGBTQIA+ people, it is important to remember that many LGBTQIA+ people, both in the past and currently, have chosen or been forced to keep their sexual and gender identities private. An individual may not speak publicly about being LGBTQIA+ for many reasons, including social prejudice and systemic pressures, but also because of personal preferences. Therefore, we cannot know with certainty who the first LGBTQIA+ person was for any achievement, and the list below of first known trans elected officials in the Unites States does not include earlier officials who might have been trans

but who were not out in their public lives, including their political careers.

However, we often think about "firsts" or historic achievements as one potential way to measure progress: If a member of a stigmatized minority group can publicly claim that identity and still be elected to public office, it suggests some degree of acceptance among a significant part of the public. As more members of that group successfully run for office, it implies growing acceptance for that group. Thus, focusing on historic achievements of people who publicly identify as trans is an important way to assess attitudes toward trans people overall. Following is a list of such noted firsts:

- In 1974, Kathy Kozachenko became the first openly LGBTQIA+ person to be elected to political office in the United States. Kozachenko, who identified as lesbian, was elected to the City Council of Ann Arbor, Michigan. Although she was not trans, her election provides important context for trans representation, as the first openly trans person was not elected for another nearly 30 years.
- Joanne Marie Conte was the first known trans office holder in the United States, but she was not out as trans when she was elected to the City Council of Arvada, Colorado, in 1991. Rather, she disclosed in 1993, after learning that she was about to be outed by a Denver newspaper. She lost a subsequent campaign for the Colorado State House in 1994.
- Similarly, Althea Garrison, who was elected to the Massachusetts State House for one term in 1992, is sometimes considered the first trans state-elected official, as well as the first Black trans state-elected official, in the United States. Garrison, however, has never acknowledged or confirmed whether she is trans in any of her more than 30 campaigns for political office (all but one of which was unsuccessful) since 1982.
- In 2003, Michelle Bruce, a trans woman, became the first openly trans person elected in the United States. She ran unopposed and was elected to the City Council of Riverdale, Georgia. During her 2007 reelection campaign, however, she was sued by political opponents who claimed that, by identifying as a woman, Bruce had committed electoral fraud. She did not win reelection.
- In 2006, Kim Coco Iwamoto, a trans woman and Japanese American, was elected to the Hawai'i State Board of Education. In doing so, she became the first openly trans person of color elected in the United States and the first openly trans person elected to statewide office.
- In 2014, Vered Meltzer became the first openly trans man to be elected in the United States. He was elected to the City Council of Appleton, Wisconsin, and has been reelected since.
- In 2017, Danica Roem, a trans woman, became the first openly trans person to be elected to and seated in a state legislature, after she defeated a 13-term Republican incumbent who was strongly opposed to trans rights. Before Roem, Stacie Laughton—also a trans woman—was elected to the New Hampshire state legislature in 2012, but she resigned before taking office.
- In 2017, Andrea Jenkins became the first openly trans Black woman to be elected to U.S. office, and Phillipe Cunningham became the first openly trans Black man. Both were elected to the Minneapolis City Council on the same night.
- In 2018, Christine Hallquist became the first openly trans person to be a major party candidate for state governor. She was the Democratic nominee in Vermont but lost the general election.
- In 2020, Sarah McBride became the first openly trans person to be elected to a state senate when she won her race for the Delaware Senate. That same night, Stephanie Byers became the first openly trans person elected to the Kansas House, and as Byers is also a member of the Chickasaw Nation, she became the first openly trans Indigenous person elected to any state legislature. Other trans firsts in 2020 included the first openly trans person elected in Illinois (Jill Rose Quinn), Louisiana (Peyton Rose Michelle), Maine (Geo Neptune), Vermont (Taylor Small), and West Virginia (Rosemary Ketchum). Additionally, Mauree Turner, a Black nonbinary person, was elected to the Oklahoma House, becoming the first known nonbinary person elected to a state legislature.

- As of 2020, no openly trans man has been elected to a statewide office, and no openly trans person has been elected governor or to any federal office in the United States.

Patterns

The number of trans elected officials in the United States remains disproportionately low. Prior to the November 2020 election, the Victory Institute reported that there were 25 openly trans elected officials across the country, out of roughly 520,000 potential offices. This means that less than 0.00005% of all elected officials in the United States are trans, despite making up at least 0.6% of the adult population, according to the Williams Institute. Put another way, greater than 3,000 more trans people would need to be elected to be commensurate with the U.S. trans population. While the November 2020 elections brought multiple trans wins, there remains a long way to go before parity is reached.

While the number of trans elected officials remains relatively low, available data and existing research show some clear patterns about LGBT candidates generally, as well as trans candidates specifically. As candidates for office, LGBT people are rated more negatively than candidates from other minority groups. They are often assumed to be more politically liberal than they may actually be, which may artificially reduce their appeal to moderate or conservative voters. Additionally, Americans are more likely to hold negative beliefs about trans people than about LGB people, and research shows that more Americans say they would oppose a trans candidate for office than say they would oppose a LGB candidate—although in both cases, a majority of people say they would "probably vote" for such a person if they shared their political views.

Research also shows that, as with women and racial and ethnic minority candidates, LGB candidates are less likely to be recruited by political parties to run for office. Trans candidates are even less likely to be recruited or viewed as electable, and this may be especially true given that elected officials and party leaders generally overestimate the conservativeness of their constituencies. Indeed, from 1977 to 2016—nearly 40 years—only 12 openly trans Americans were successfully elected to office. Only two were elected to a statewide office, and one of them resigned before taking their seat. The remaining 10 were all elected to a local office. This demonstrates the remarkably low incidence of trans elected officials in the United States, but it also shows the importance of studying local representation, as the vast majority of trans elected officials in the country to date have served at the local level.

However, those who are elected have the power to make a difference. Research shows that state legislatures with a greater number of LGBT elected officials are more likely to introduce and adopt LGBT-supportive bills, even controlling for other factors, and having openly LGBT legislators has a positive influence on the beliefs and behaviors of non-LGBT legislators. Given that significantly fewer Americans report knowing a trans person than knowing an LGB person, this effect may be even stronger when a trans person is elected to office.

Demographically, trans candidates (both those who win and lose elections) are far more likely to be white than people of color, as is the case with U.S. candidates for office more generally. However, in contrast to the demographics of U.S. candidates overall, trans candidates and elected officials are more likely to be women: In 2020, 20 of the 25 trans elected officials in office were trans women. Additionally, whereas research shows that LGB candidates for office are generally more likely to run and be elected in urban areas, many trans candidates have run—and some were elected—in smaller, sometimes suburban or rural districts, such as Ralston, Nebraska; Hiawatha, Iowa; and Doraville, Georgia.

As the acceptance of trans people grows, trans candidates may become both more numerous and more successful in their bids for office. And as trans candidates become increasingly successful, more trans candidates are likely to emerge in turn, encouraged by the success of their peers. After Danica Roem, Phillipe Cunningham, and Andrea Jenkins—as well as five other trans people—won their elections in November 2017, a wave of trans people announced their candidacies for various local, state, and even national offices. In 2018, at

least 9 more trans people were elected to office, with at least 13 more elected (or reelected) in 2019 and another at least 12 more elected (or reelected) in 2020.

Representation in government is only one way to gauge progress or political power, but it is a way that gives insights into who is, or is not, involved in the many decisions about the laws and policies that shape our day-to-day lives.

Electoral Politics

Trans rights issues are sometimes raised in electoral politics. Electoral politics encompasses political representation through the election of legislators and executives. It also includes forms of direct democracy, such as ballot initiatives and referendums. In democratic systems, it is important to understand how elected officials and voters view trans rights, as these actors are vital in securing many types of policy changes desired by trans communities or by their opponents. This entry discusses three aspects of trans rights and electoral politics: trans candidates, trans issues in election campaigns, and ballot measures directly addressing trans issues.

Trans Candidates

The trans community in the United States is numerically very small (less than 1% of the population) and remains socially marginalized. As such, relatively few openly trans candidates have entered the electoral arena. Indeed, the world's first openly trans candidate to win a seat in a national legislature, Georgina Beyer, was elected to New Zealand's parliament in 1999. Yet, an increasing number of openly trans people are running for office at different levels of government. For instance, in 2017, two openly trans candidates, Andrea Jenkins and Phillipe Cunningham, won local races for city council in Minneapolis, Minnesota. That same year, Danica Roem defeated archconservative Bob Marshall for a seat in the Virginia House of Delegates, becoming the first openly trans person elected and seated as a state legislator in the United States. Finally, in November 2020, Delaware elected the country's first openly trans state senator, Sarah McBride. These victories are advances for the trans movement because they not only highlight increasing levels of social and political acceptance for trans people but also increase descriptive representation in government (that is, having elected officials who share identities with their constituents). This potentially bodes well for trans people, since increases in descriptive representation for other political minority groups, including women and racial and sexual minorities, tend to correspond with increased responsiveness to their policy demands.

Research suggests that trans candidates face hurdles similar to those of lesbian, gay, and bisexual (LGB) candidates. Older, conservative, religious, less-educated, male, and Republican voters are less likely to support LGBTQ+ candidates. However, voters are more likely to oppose trans candidates relative to lesbian, gay, or bisexual candidates. Psychological and emotional factors that shape general attitudes toward trans people, such as disgust sensitivity, authoritarianism, and the relative need for cognitive closure (i.e., aversion to ambiguity), may also reduce voters' willingness to support trans candidates.

Thus, like LGB candidates, potential trans candidates need to strategically select their districts to maximize their chances, prioritizing highly

educated, Democratic-leaning areas and places where there are open seats or unpopular incumbents. Trans candidates might also be more successful by raising their profile with Democratic-leaning groups and with community organizations to increase name recognition and create allies. In addition, they should expect their trans status to be a potential vulnerability that primary or general election opponents may attempt to exploit.

Trans Issues in Election Campaigns

Apart from the candidates' gender identities themselves, trans issues can also be featured in election campaigns, both prospectively and retrospectively. In prospective voting models, voters choose candidates based on expectations about their future actions. Conversely, retrospective voting looks at past performance of the candidate. Candidates that have taken actions to oppose or restrict trans rights, like North Carolina Governor Pat McCrory, are sometimes retrospectively punished by voters for their stances. Such directly attributable punishments related to trans issues, for or against, have been rare in general elections. Still, McCrory's loss in 2016, following his role in passing a law that based public bathroom access on the sex listed on a person's birth certificate (HB2), put opponents of trans rights on notice that such explicit and high-profile opposition to trans rights may not be cost free. Conversely, given the small size of the trans community, there are few prospective rewards, on average, for making pro-trans stances central to a general election campaign. Candidates must speak to the wants and desires of a greater number of voters.

The utility of trans rights as a campaign issue is subject to locally relevant forces and public attitudes on LGBTQ+ rights, which vary by jurisdiction and by issue. Nevertheless, Republican candidates for office may feel pressure to oppose trans rights, while Democrats may be compelled to be supportive. Republicans rely heavily on religious conservatives who commonly oppose LGBTQ+ rights, whereas LGBTQ+ voters are an important Democratic constituency. Indeed, it was criticism from LGBTQ+ activists and donors that pressured President Obama to become more supportive of same-sex marriage (an issue that affects many trans people in relationships) during his 2012 reelection bid.

In certain instances, candidates and parties may attempt to use trans-related policy as a wedge issue in campaigns. This was likely part of the intent of North Carolina Republicans in advancing HB2. They believed it would put the state's Democratic attorney general (and gubernatorial candidate) in a political bind following his refusal to sign an amicus brief that opposed trans students using gender-aligned restrooms in *Grimm v. Gloucester County School Board*. In addition to policies around trans bathroom access, other potential wedge issues are public funding of medical treatments for trans people who are transitioning and trans participation in athletics. Surveys show that there is less public support for these issues than for employment or housing nondiscrimination protections and allowing trans military service.

At the same time, actions by presidential administrations signal stances to their constituencies and to other elected officials, exacerbating the partisan divide. For example, the Obama administration issued guidance on Title IX in order to make school facilities and athletics more trans inclusive and changed Department of Defense policy to allow trans people to serve openly in the military. The Trump administration, however, moved policy in the other direction, reinstating the trans military ban, withdrawing the Title IX guidance, and asserting in court that Title VII sex discrimination protections do not apply to gender identity. The Biden administration subsequently reversed the Trump era changes. As these contrasting positions on trans rights issues become more crystallized within parties, elected officials who deviate from party orthodoxy may become ripe for primary challengers, particularly among Democrats. For Republicans, there is likely a greater risk in adhering to the demands of party activists, given the long-term trend for increasing public acceptance of sexual and gender minorities.

Direct Democracy

Direct democracy institutions give voters the ability to vote directly on public policy, rather than indirectly through the election of officials. These institutions include ballot initiatives, where policy proposals are generated and voted on by the public; referendums, statutes, and amendments passed by a legislature that are referred to the voters; and recall elections. Not all states have an initiative or referendum process, and there is considerable

variation in the rules for qualifying and passing a ballot measure at the local level. In the United States, there is no process for initiatives or referenda at the national level.

Since these institutions empower voting majorities, direct democracy has long been the bane of historically marginalized LGBTQ+ communities. For instance, Anita Bryant successfully worked to overturn a local gay rights ordinance in Dade County, Florida, in 1977 via the referendum process. In 1992, voters in Colorado approved a measure, Amendment 2, which banned any legislative, executive, or judicial action in the state that would make sexual orientation a protected class under laws banning discrimination. Similarly, during the 2000s, voters in a majority of states passed constitutional amendments banning same-sex marriage. Perhaps the most high-profile of these measures was Proposition 8 in California (2008), which reversed existing state policy. Although Amendment 2 in Colorado and the state constitutional bans on same-sex marriage were later overturned by decisions of the U.S. Supreme Court—in *Romer v. Evans* (1996) and *Obergefell v. Hodges* (2015), respectively—opponents of LGBTQ+ rights commonly try to expand the scope of conflict to the electorate when engaged in fights over LGB and trans rights. Ballot issues, such as marriage bans during the 2004 presidential election, have been tactically employed in an effort to increase election turnout by conservatives.

Despite how ballot measures have historically been used to restrict LGB rights, the track record for trans rights when facing direct democracy is more mixed. At the local level, opponents of trans rights have had some success in reducing trans rights to the issue of bathroom access, which they then frame as a safety concern for women and children. Such bathroom-focused tactics were successfully deployed in Houston, Texas, during a 2015 referendum on an ordinance that included antidiscrimination protections for LGB and trans people. Voters overwhelmingly rejected the ordinance. However, this safety framing around bathrooms is not guaranteed to produce success. In 2018, voters in Anchorage, Alaska, narrowly rejected a ballot initiative that defined sex as an immutable condition defined by anatomy and genetics at the time of birth and that would have allowed employers to create and enforce sex-specific policies related to restrooms and locker rooms. Furthermore, in a 2018 referendum in Massachusetts that challenged the state's expansion of public accommodations protections to trans people, voters overwhelmingly upheld the trans-inclusive law by a vote of 67.82% to 32.18%. Had trans rights supporters lost this vote in a liberal state like Massachusetts, the prospects for future legislative advances would have been dimmed and opponents to trans rights would have been encouraged to attack other trans rights gains using the ballot box. On the other side of the issue, trans rights activists have not used the initiative process to pursue policy goals at the state level. This may be driven by the tendency of direct democracy institutions to increase the responsiveness of elected officials to citizen preferences. Therefore, in states where the public supports trans rights and ballot initiatives are available, the legislature has likely already moved policy toward trans rights, negating the need for proponents to pursue these policies directly at the ballot.

Future Directions

Trans rights will likely remain an issue in electoral politics for the foreseeable future. Depending on the local or state context, trans issues may be a salient topic that can be deployed as a wedge issue. Restroom access policies and public funding for trans-related medical treatments remain controversial, and support for trans people and trans-friendly policies will vary by jurisdiction. Trans candidates can win elections, but they face many of the same hurdles that LGB candidates face but with even lower levels of public acceptance. However, pressure from LGBTQ+ groups has increasingly forced Democrats to be more inclusive of trans rights, and trans advocates are winning an increasing number of challenges in the referendum process. While the road to progress on trans rights through electoral politics is far from clear, it is not blocked either.

Embodiment

All living things have a body, a container that consists of muscles, sinew, blood, water, skin, microbes, and more. Awareness of this body and history of this awareness alert to all its meanings and changes is what becomes one's sense of embodiment: to become a self through knowledge of a bodily being encountering other embodied beings. This sedimented bodily sense for humans is an ordinary, banal, mundane accompaniment as much as an accomplishment. However, the gritty, layered meaning of morphology and built-up proprioception can become pushed forward into agreement or conflict with other "social facts" like gender, race, (dis)abilities, and age that hook into or zip up one's embodiment. This entry considers how Trans Studies scholarship, some anchored in the embodied knowledge of trans persons, has developed important theories of time, space, difference, subjectivity, and more according to lived experiences. It does so while examining how this scholarship builds on diverse traditions in critical race theory, media studies, queer sexuality, and feminist theory that center the body.

What Is a Body?

What is it to be a bodily being, sentient, woven into the world? This is a philosophical question but also a practical one. Freudian theories look at bodies as vectors of drives—for pleasure but also for death—in which a body is organized through desire lines that cathect it with other bodies and objects. The poststructuralist development of linguistic theories for subjectivity has an elaborate framework for understanding "bodily inscription" in which the matter of bodies cannot be thought separately from the discursive impressions, self-carvings, and the intelligibility of the ruling episteme. Philosophies of perception such as phenomenology, cognitive sciences, and their elaboration in dance and choreography know-how would say that spatial orientation, rhythm, and kinesthetic sense ground subjects in their bodily flesh. These fields attempt to reconcile how to weight combinations of psychic–corporeal, matter–language, affective thrumming, and felt sensibility. The ontological question of trans bodily knowledge can never be settled, for there is no one way to experience being "trans"; however, the combined attempts at working from the subjective sense of self offer important inroads to grasping what a body is through the trans prism of

experience. Trans bodily knowledge is an optic for analysis: the intersectional analysis of sex, gender, race, age, (dis)abilities, linked to analyses of health, vulnerability, care; of sexuality, desire, erotics; of language, discourse, and *dispositifs*.

Body Politics and Identity Politics

The question of what makes a body "trans"—in the widest possible sense—has echoes in other discussions: What is a woman, what is it to be Black, and how do we think about bodies before colonialization, before modernity, or according to religion? The ways in which embodiment differs, therefore, is not only about considering the single person's body but how sociality tethers one to their body in shared, collective, but also forceful ways. The measure of difference between embodiments therefore has critical importance.

Since the dawn of Eurocentric Enlightenment thinking, sexo-psychic medical discourses have had a hegemonic grip on trans embodiment. Their ascension into being a proper "science" has been assisted by the creation of taxonomized categorizations that separate the normal from the abnormal. The legacy of proper naming and recognition for sex/gender/sexuality differences—invert, psychic hermaphrodite, transvestite, transsexual, gender identity disorder, homosexual, or autogynephilia—is being actively challenged by the depathology movement, which places value on the wide variety and diversity of sexed and gendered embodiment. These movements for self-determination push back on the presumed authority of "scientific expertise" while challenging its legacy of misnaming, misrecognizing, and misusing differences of sex, gender, and sexuality that so often coincides with racialization/racist epistemological paradigms.

Discussions within the field of Trans Studies differentiate embodiment according to how the optic of gender might operate differently from that of sexuality, namely, via queer theory with its roots in gay and lesbian studies. The so-called border wars, as a key publication dossier in a 1998 issue of *GLQ: Gay and Lesbian Quarterly* called them, examined the fraught understanding of the difference between masculine embodiment understood as lesbian butch and as female-to-male transsexual (FTM or F2M) in the language of 1990s discourses. This discussion often referred to the historical figure of Brandon Teena, who was murdered for daring to take liberties and pleasure in their masculine embodiment as an assigned-female-at-birth (AFAB) person. The violence of Brandon's death was reenacted in the fight over claiming their body for different communities. The proffered notion of a *continuum* of masculinity brought about more debate regarding the self-assessment of one's trans status and respect for gender expression, identity, and in one's gender attribution, for instance, through pronouns and use of a chosen name. The prefixal expansion of trans* with the asterisk multiplier that became popularized in the mid-2000s challenged the legacy of being perceived as "trans enough" to claim the identity within various social circles.

Impact on Theories of Time, Space, and Media

Employing a trans optic on questions of embodiment allows the researcher to consider how to extrapolate from common experiences to comment on a generalized condition and even overturn previously held assumptions. For instance, the experience of "gender transition" can be parsed in multiple discipline-specific ways: as a period of time, a technological feat, a medical hurdle, a legal fix, a personal psychological trajectory that remains in play. At its core, examining accounts of gender transition raises questions of what is the duration of transition, for whom is the transition sudden or continuous, and which authorities and acts are involved in a transition? The quality of one's "transition time" might operate according to different temporalities than, say, the typical transitions of life as one ages, because of markers like the change of name or reintroduction to kin, the start of hormone treatment, and physical changes that induce a second puberty. Although specific rules apply to trans persons, similar transitions occur when someone marries or undergoes menopause. The embodiment of trans time then might be fractured, discontinuous, and layered: At any rate, it goes against the presumption of a linear, enduring sense of self-sameness associated with a cis identity.

Related to the axis of time, the spatial orientation of transness both locally and in terms of a geopolitics of location has shifted scholarship in sociology, anthropology, political science, and more. In the early period of writing on trans embodiment, researchers turned to non-Western

contexts to confirm the sameness of trans experience or show the potential for locating "third gender" options that may be imported back to the West/global North. The critiques of these attempts, such as pointing out how they "romanticize the Native" or form a colonial mentality within the transgender imaginary, have been essential to making Trans Studies sensitive to how space interacts with identity formation: appropriation in assumed proximity or exotification through distancing or denial of coeval-ness. The erasure or misuse of specific local nonwhite or non-American/European terms such as *queen, tranny, aggressive,* or *hijra, waria,* or *fa'afafine* also requires thinking through the spatial axis in embodiment practices as transmitted through the use of dialect and vernacular language.

A third issue is the coalescing of trans identities alongside modernization, with the threat of temporally and spatially distancing those in premodernity versus postmodernity. As electronic, digital, and computational technologies have driven many instances of modernization, scholars have been interested in parsing the ways in which embodiment has been affected by newfound experiences of these media (also in relation to older forms). Feminist film theorists have long argued for the key role that bodies play in interpreting images, centering a corporeal rather than a cognitive engagement. The launch of the Internet 1.0 and 2.0 has also made for new means to engage an immersive bodily experience. While "cyberspace" was hailed as a meat-free space of freedoms in which identity might be adopted at will, these dreams have been tempered by a turn to acknowledge the extractive process of user tracking, data mining, and how algorithms direct online behavior. Sandy Stone's "The Empire Strikes Back: A Posttranssexual Manifesto" in 1987 described the programmable grammar of gender and presaged many theories about digital embodiment, such as its updateability and modulation.

Bodying Forth?

The field of cultural studies and cultural critique has also been a rich site for thinking through the optic of trans embodiment, particularly by examining the values placed on bodily change. Transness has most often been exploited for its spectacular features, so as a spectacle that might induce horror or arousal. Rarely has trans embodiment been allowed to remain background noise, the mundane experience of one's gendered body. In trans cultural production, as in popular and mainstream venues, the increasing visibility of (some) trans bodies in narrative and documentary media has transformed the media landscape. What do (some) trans people gain from shifting from being relegated to the laughingstock on talk shows to playing the protagonist of a dramatic feature? Historians, such as Joanne Meyerowitz in 2001, show that media representation can produce a "shock of recognition" that assuages isolation and fosters community formation. As an actress and leading voice in cultural politics, Laverne Cox has called media presence a significant mode to present "possibility models" for being trans. How might producers, creatives, and viewers each and collectively "body forth" the horizon for actualizing trans embodiment?

The language of the human right to self-determination, as used in parts of the transgender movement, overlaps with the struggle of decolonial, feminist, and race equality social movements. Within a neoliberal framework, the notion of self-determination might be reduced to being able to privately access surgical procedures (modifications and enhancements), which tends to mistake the self in "self-determination" to be a wholly autonomous private citizen. The body's vulnerability to others requires scholarship in Trans Studies to think more expansively about accomplishing self-determination as a collective act. Thus, acts of bodily liberation link up prison abolition with gender abolition; the continuous accomplishment of that bodily freedom in use and mobility requires others to be accomplished. Embodiment is a collective feat. Hence, Trans Studies has often advocated the refusal to be just a body—to the law, to medicine, to a disciplinary study, or on display in media—and to instead foster awareness of *this* unique body situated within a wider context. Embodiment is a powerful concept because it facilitates attentiveness to the history of embodiment, alert to all its meanings and changes wrought through and with our encountering other embodied beings.

EPIDEMIOLOGY

Epidemiology is the study of the distribution and determinants of health and disease in populations. Epidemiologists ask, Who gets sick, where, when, and why? Trans individuals and populations were largely invisible in published epidemiologic studies until the 2010s. Trans status was not ascertained in most of the data sources used in epidemiology—and still is not, in most places and cases. Furthermore, early epidemiologic research often focused on the prevalence of transness (classified as a psychiatric condition) rather than on the health of trans populations. The rapid growth in epidemiologic research on trans people may be attributed to two interrelated processes: the depathologization of trans identity and the increased recognition of gender identity as a dimension of human diversity that is associated with health because of societal stigma and oppression. For example, in 2016, the U.S. National Institutes of Health formally recognized gender minorities as a "health disparity population."

Descriptive Epidemiology of Trans Health

Descriptive epidemiology aims to accurately estimate the prevalence (proportion of the population with a condition) and incidence (number of new cases over time) of health conditions and their distribution across the attributes of person, place, and time. Descriptive data are used to identify health inequalities, allocate resources, and generate causal hypotheses. Accurate descriptive epidemiology requires data from representative samples of the population or from the entire population. In a few countries, population-based surveys (which use probability sampling to obtain representative samples) and public health surveillance systems have started to add questions to identify trans respondents. For example, in 2014, the U.S. Behavioral Risk Factor Surveillance System (BRFSS) introduced an optional (at the state level) module on Sexual Orientation and Gender Identity (SOGI). These data have been used to identify inequalities in mental health, chronic illness, and health behaviors between trans and cis people. They were also used by the Williams Institute in 2016 to estimate the proportion of adults in the United States who identify as trans (0.6%).

Defining and Measuring Trans Status

Describing the health of subpopulations such as trans people also requires that membership be defined and operationalized in a consistent and valid way. Continuing with the example of the BRFSS, trans status is measured with a question that reads, "Do you consider yourself to be transgender?" Such a question may not capture individuals who have a gender that differs from their assigned sex at birth but do not identify with the term *transgender*. Furthermore, the survey logic assigns questions about sex-linked health issues (e.g., cancer screening) based on the interviewer's initial assessment of the respondent's sex, potentially leading to misclassification bias. Epidemiologists have evaluated various approaches to ascertaining trans status in population health research and generally recommend the "two-step" approach in which sex assigned at birth and gender identity are queried separately and then cross-classified to identify cis men and women, trans men and women, nonbinary people assigned male at birth, and nonbinary people assigned female at birth. Population-based surveys have been slow to adopt this recommendation, but Statistics Canada began testing a "two-step" question format in their surveys in 2018.

Community Surveys

It is important to note that while population-based surveys and surveillance data are the gold standard for descriptive epidemiology, nonrandom "convenience" samples of trans communities have generated critical insights about trans health. For example, the 2015 United States Transgender Survey (which surveyed more than 27,000 trans people) found, consistent with previous convenience samples, that 40% of respondents had ever attempted suicide, compared with less than 5% in the U.S. population overall. Although the precise magnitude of the disparity might differ with population-based data, a large disparity would undoubtedly persist, and thus these data are crucial for motivating public health action. To increase the representativeness of community-based surveys, researchers have also used approaches that could be considered "quasi-probability" sampling, including time-location and respondent-driven sampling, which involve systematic recruitment through venues and social networks, respectively.

Health Systems Data

Health system data represent another important source of epidemiologic data on trans health. These studies use electronic health records within community health centers, health insurance systems, and integrated health care systems. At present, electronic health records rarely capture consistent data on sex assigned at birth and gender identity; however, diagnostic codes and keywords can be used to ascertain likely trans individuals. Such studies have the advantage of being able to compare health outcomes and care utilization between trans and cis people, although findings are only applicable to trans people who have access to health care.

Analytic Epidemiology of Trans Health

Analytic epidemiology is concerned with estimating the causal effect of exposures—be they medical treatments, social factors, or policies—on health outcomes. Internal validity is key to analytic studies and depends in large part on the comparability of the groups being compared according to measured and unmeasured characteristics; for this reason, randomized controlled trials sit atop the epidemiologic "hierarchy of evidence." Nevertheless, randomized trials have been rare in trans health research. While many questions in trans health cannot ethically or feasibly be evaluated through trials (e.g., whether providing hormone therapy improves mental health), some important clinical questions could be evaluated (e.g., comparing hormone regimens). Among observational (i.e., noninterventional) study designs, strictly speaking, only longitudinal studies allow for causal inference because the order of cause and effect can be determined, whereas in cross-sectional studies, exposure and outcome are measured simultaneously. As trans health research has historically received limited funding and trans people have not been substantively included in non-trans-specific longitudinal studies, most trans health research to date has been cross-sectional.

The Future of Epidemiologic Research on Trans Health

There has been remarkable growth in quantitative trans health research in the second decade of the 21st century. The overwhelming majority of data, however, comes from a handful of high-income countries. Although trans people experience the same range of health concerns as cis people, trans-specific epidemiologic research has concentrated on mental health, HIV, and substance use. In addition to addressing methodologic challenges related to measurement, sampling, and study designs, the future of epidemiologic research on trans health will involve expanding the range of questions investigated and the geographic diversity of trans populations included in research.

Epistemologies

Epistemology is the philosophy of knowledge and its production, sources, scope, structure, methods, and conditions. There are different, often contested ways of knowing and accounting for that multiplicity necessitates the plural: *epistemologies*. Epistemologies examine the how, what, why, where, and who of knowledge. In challenging the ways of naming, describing, and knowing gender and its relationship to embodiment, Trans Studies has been concerned with epistemologies since its inception. Some even argue that trans existence—that is, the assertion of one's gender as different in some way from that assigned—is inherently an exercise in confronting the epistemological limits of cisnormative gender and thus always a practice of critique. Trans engagement with epistemic questions, on one hand, formulates correctives to established, often disciplinary bodies of knowledge and, on the other hand, is generative of trans epistemologies. In their critical mode, trans epistemologies question the knowledge production *about* trans people and phenomena that takes them only as the objects of knowledge. Such critiques often focus on the pathologization and marginalization of trans ways of being, the extraction and appropriation of knowledge for research, the scapegoating of trans examples for failing to more fully resist gender norms or for failing to adhere to them, and the objectification of trans subjects. Other critiques target cisnormative knowledge production that erases trans existence and discredits or outright excludes trans knowers—knowledge not about but *without* trans. Both of these critiques can be framed in terms of epistemic injustice. While in the mode of critique they address epistemic injustices, trans epistemologies redress them by theorizing trans ways of knowing, knowers, methods, and the production of trans knowledge as epistemologies in their own right, often paying particular attention to embodiment, positionality, and experience.

Epistemic Injustice

Epistemic injustice, a concept that names injustices related to knowledge and knowledge production caused by the effects of social power, is often used to describe the work of trans epistemologies as critique. Epistemic injustice can affect the knower, when knowledge claims are dismissed based on prejudice against the identity or status of the knower (testimonial injustice). The dismissal of trans self-knowledge by others and the valuation of expert gatekeepers over trans voices in granting access to transition-related medical care or gender marker changes are examples of testimonial injustice. While cisgender assumptions and experiences are often granted the status of the seemingly obvious or privileged as commonsense for which no justification is necessary, trans knowers are held to standards of justification that are designed to dismiss their claims and exclude their knowledge from even being considered as such. Epistemic injustice also affects the knower when people are denied the interpretive and conceptual resources of becoming a knower, of making sense of their experience to themselves and others (hermeneutical injustice). Criticizing the exclusion of trans knowers from academic or activist institutions of knowledge production, distribution, and authority is an example of how trans epistemologies address hermeneutical injustice. Epistemic injustice can also be content focused, when claims are denied because their content relates to trans issues, even when articulated by knowers otherwise privileged. This affects what can be known, is known, and is counted as knowledge in ways that lead to a distortion of trans as an object of knowledge. Whereas objectification—being known and studied in terms of a mere object of curiosity, pathologization,

and/or appropriation—is one of the injustices criticized by trans epistemologies, there is also injustice to being an object of willful ignorance or deemed unworthy of knowledge production or irrelevant to its scope. Being reduced to a mere object of knowledge is dehumanizing, but being the object of too little or no research or being excluded from existing research, and thus facing widespread medical ignorance of the specificities of some trans bodies, surgeries, or therapies, is also a form of epistemic injustice.

Trans Epistemologies

In their concern with experience, oppression, and situated knowledge, trans epistemologies intersect with other critical epistemologies such as feminist, indigenous, queer, disability, and critical race ones. Such epistemologies consider marginalized forms and ways of knowing—knowing otherwise or differently, the knowledge emerging from oppression and survival—the effects of epistemic injustice, and they theorize the epistemic consequences of privilege, as in the epistemology of ignorance. The epistemic consequences of the status of ally have attracted particular attention in trans epistemologies, too. Some critics are concerned that it can be used as a position of unearned epistemic privilege that can disguise epistemic violence, including the discounting and gaslighting of trans knowers. Others emphasize that ally privilege can be used to challenge epistemic injustice, and allies can face content-focused epistemic injustice when speaking on trans issues, even if the epistemic harm of misrecognition falls squarely on trans people.

Focusing on trans knowers, some scholars formulate identity-based epistemologies, in a "for us and by us" approach, whereby trans knowledge is related to being trans. Others suggest that trans epistemologies go beyond experiential knowledge, beyond trans subjects, and are rooted in thinking trans, in using *trans* as a verb for a conceptual move, or in tracking historically, regionally, and culturally variable and specific ranges of gender, sexuality, and embodiment. Many hold the two approaches to be complexly related, so that trans epistemologies take lived embodiment and positionality as the active locations of the social, relational, and affective emergence of trans identities and knowledges that dominant epistemologies often render unnameable and unintelligible. What they all have in common is an interest in looking beyond cisnormative rules of legitimate knowledge (both in the form of common sense and of expert discourse) and toward the epistemological potential of taking trans voices as well as trans knowledge production—in the broadest sense—seriously.

Trans Epistemologies Across the Disciplines

Whereas *epistemology* as a term originates in philosophy and travels along the route of theory into humanities and social sciences, trans epistemologies are relevant to many different areas of knowledge production and across disciplines. Trans Studies scholars have taken this perspective to an ever-growing list of fields and disciplines, including anthropology, history, legal studies, medicine, public health, social science, film studies, literary studies, higher education, and many others. Wherever they appear, trans epistemologies tend to suggest different priorities, sites of inquiry, and questions.

Based on their epistemological critique of existing research, some scholars offer specific guidelines for human subjects research with trans participants, engaging with the ethical and practical processes of a certain kind of disciplinary knowledge production. Others argue that, since academia has long excluded trans and other knowers, the knowledge production process itself must be transformed: Activist and experiential knowledge need to be taken seriously in their epistemological value, need to inform research design, and need to shape how research is held accountable to communities.

Human subjects research is not the only kind of knowledge production analyzed with trans epistemological tools in various disciplines. In legal studies, for example, trans epistemologies question the cisnormative framework of how law constructs gendered legal subjects and challenge the epistemically unjust effects of legal discourse on trans litigants and trans rights. In sociology, some trans epistemologies foreground how subjects position themselves in relation to culture, institutions, and communities in often contingent, iterative, and relational ways that do not signal a lack of self-knowledge but are instead understood as carefully crafted negotiations of meaning. In anthropology, epistemological questions are raised about how *transgender* as a term travels globally through

U.S.-dominated economics of knowledge production, is exported, and is both taken up and resisted in locally specific ways as it encounters other local and/or historical epistemologies.

In the field of higher education studies, Z Nicolazzo in 2017 posited six tenets for imagining a trans epistemology, including attention to oppression as a shaping force of trans epistemology, to varied experiences and intersectional identities, to the role of trans community, to material and virtual environments, to activism and grassroots organizing, and to the problem of in/visibility. Nicolazzo specifies that the first tenet means that trans people may be from oppression but not of oppression, characterizing an epistemology that is shaped by both experiences and histories of oppression but not limited to them. This echoes Leslie Feinberg's insistence that being oppressed does not make trans people the product of oppression. It is worth noting that in relation to oppression and to gender dysphoria, some trans epistemologies foreground negative experiences and negative affect in particular as important ways of knowing. While the term itself is highly contested in trans studies, that very debate marks its continuing influence on many trans epistemologies: Gender dysphoria here is at times affirmed as a source of knowledge deeply and negatively felt, at times denied as a pathologizing label of medical knowledge, at times rejected as a divisive tool of boundary drawing between a range of trans experiences, and at times redefined to reclaim the role of the trans voices that were involved in the sexological shaping of the diagnostic language.

In the humanities and cultural studies, scholars tend to formulate trans epistemological ideas by tracing trans knowledges through interpretations of artistic expression, survival tactics, contested metaphors (from the wrong body to the monster), aesthetic form, questions of representation, and cultural meaning making. These approaches argue that while trans knowledges are subjugated and have been excluded from dominant discourse, these epistemologies are productive of, and can be gleaned everywhere from acts of, trans worldmaking, interpretation, and imagination.

In all fields and disciplines, even those most removed from any discussion of explicitly trans issues or topics of knowledge, concerns over institutional exclusion of trans knowers, its highly intersectional effects, and the rarefied privilege of access to the time, resources, and authority of academic knowledge production remain important material issues of epistemic justice.

Erasure

Trans erasure refers to an ongoing sociohistorical process whereby cis people, individually and collectively, deny, ignore, dismiss, minimize, or otherwise render invisible the existence and experiences of trans people. Even though trans people have existed in every documented historical and

cultural moment, although named in various ways over time, trans erasure allows cis people to experience social life unaware of trans experience while also referring to any observation of trans life as something "new," "unusual," or otherwise "unexpected" whenever such examples slip into mainstream social and political discussions (e.g., media, religious, scientific) over time. In this way, cis people are allowed to inhabit a "cisgender reality" predicated upon the marginalization of trans lives, knowledges, and experiences.

Importantly, this is not an uncommon process in social systems. Nor is it a process limited to trans populations, experiences, and histories. Rather, social authorities generally design and disseminate selective versions of science, religion, and media that emphasize some elements of social life (e.g., cis experience, hetero- and monosexuality, upper-class experience, endosex [i.e., non-intersex] categorization) and downplay or otherwise erase other aspects of social life (e.g., Blackness or other non-white racial experience, trans experience, bi-pan-queer-asexual-lesbian-gay sexuality, lower- and working-class experience, intersex categorization). This is generally accomplished through the limitation of marginalized voices in mainstream media, science, and religious narratives as well as the creation of white, cis, hetero- and monosexual, upper-class, and endosex-based (i.e., male or female only, non-intersex) scientific, religious, and media representations of "reality," or what a given social world is and how it works.

For example, the vast majority of religious traditions are predicated upon a cis reality wherein a higher power created two and only two sexes—that is, endosex categorization as only male or female in the eyes of the higher power—which are required by that higher power to become the two and only two genders associated with those sexes (i.e., cis socialization wherein males must become men and females must become women). From this original erasure of intersex and trans existence, such religious traditions then often demarcate every aspect of reality and the practice of their religion along cis and endosex lines. Furthermore, they punish and otherwise marginalize any example wherein a member of their religion rebels against their assigned sex and gender at times and/or over time. In this way, religions erase trans existence from their creation of reality and maintain said erasure through their ongoing activities.

At the same time, trans people experience a similar pattern of erasure and punishment in scientific traditions. When establishing and creating surveys for understanding the broader social world, for example, scientific disciplines generally mirror religious traditions by assigning all participants as only male or female (endosex categorization) and extrapolating cis gender construction (i.e., the males are coded as men, the females are coded as women) from these assignments. Although some exceptions to this pattern have begun to emerge, most social scientific surveys create and disseminate a cis version of what the world looks like within their scientific disciplines. In fact, one may see a similar erection of cis- and endosex-based notions of the empirical world in the norms used throughout the sciences to identify everything from animals and plants to social structures and neural networks within the human brain. In all such cases, mainstream scientific practices erase trans (and intersex) existence to establish a version of the natural world that both matches dominant religious stories and promotes cis-only worldviews.

The combination of these processes of trans erasure can be seen by all members of the social world, regardless of religious tradition or scientific access, through media representations. In fact, an example of such patterns can be found in recent increased media attention to trans experience that almost entirely defines such experience as "new" despite the plethora of evidence, sometimes even from past content delivered by the same media outlets, to the contrary. In the case of trans reproduction, for example, some of the same news organizations that covered trans pregnancies in the late 1990s and early 2000s then defined these same types of stories as "new" phenomena when covering trans pregnancies in the 2010s. As has been common in relation to cis women, as well as racial, sexual, class, and religious minorities, news media typically reflect and reproduce existing scientific and religious norms in a given society and across the world. Rather than capturing the actual social world that cis, trans, and otherwise gendered people inhabit, the media have thus typically limited their representation of society to cis-only phenomena. As such, even the greater representation of recent years typically contains false assertions that

trans people are a "new" part of society and only provides limited portrayals (in terms of race, class, sex, gender identity, sexualities, religion, and other aspects of social identity) of trans populations.

In each of these examples and in many other cases, contemporary social norms rely upon and generally reproduce longstanding patterns of trans erasure. In so doing, these social authorities make it both more difficult for trans people to see and understand themselves through media, religion, or science and easier for cis people to minimize, ignore, marginalize, or otherwise deny trans existence in their own individual and collective lives. Rather than maintaining narratives reliant upon trans erasure and the maintenance of cis privilege, understanding ourselves, gender itself, and even society more broadly requires recognizing and representing the existence and multitude of experiences of trans people throughout the world. It requires combatting and otherwise undoing trans erasure.

Erickson, Reed

By way of the Erickson Educational Foundation (EEF), Reed Erickson (1917–1992) directly or indirectly supported almost all public education, research, peer support, and activism about trans people during the years the EEF was active in that area (1964–1976). He also made major contributions to the early homophile organization ONE Inc. and to "New Age" spiritual groups.

Reed Erickson grew up in Philadelphia in a white middle-class family. After secretarial training and a number of short-term jobs, Erickson moved to Baton Rouge, Louisiana, to work in the family lead smelting business there and, in 1946, earned the first mechanical engineering degree awarded to a woman at Louisiana State University. Unable to get work as a woman engineer, Erickson passed the next 10 years traveling and doing a variety of jobs, finally taking on a leadership position in the family business. Erickson proved to be a savvy businessperson who also inherited wealth and made some lucky land purchases that yielded significant wealth after oil was discovered on them.

Over the second half of the 1950s, Erickson began his transition by taking testosterone. By 1963, he had become a patient of Harry Benjamin, now widely considered to be the "father of transsexualism," and had his birth certificate, passport, and driver's license changed to male. Surgeries followed 2 years later. During his lifetime, he married several times, two of which were fully legal, three of which happened under unclear circumstances. With his wife Aileen, he became father to two children. Over the years, he lived with his family and his pet leopard, Henry, in Baton Rouge; later, in an opulent custom-built home in Mazatlán, Mexico, which he dubbed the Love Joy Palace; and, still later, in Southern California. Sadly, by the time of his death in 1992 at the age of 74, he had become addicted to ketamine and cocaine and died in Mexico as a fugitive from U.S. drug indictments.

During his lifetime, Erickson made huge contributions through the work of the Erickson Educational Foundation (EEF), started in June 1964. The EEF's goals, stated in a promotional brochure, were "to provide assistance and support in areas where human potential was limited by adverse physical, mental or social conditions, or where the scope of research was too new, controversial or imaginative to receive traditionally oriented support." The EEF funded in three major areas, starting with almost 20 years of core funding to the early homophile organization ONE Inc., which, in 1984 and 1985, granted the first

graduate degrees in Homophile Studies in the United States. ONE has since evolved into the ONE Archives, the world's largest LGBTQ archives. The EEF's final phase of funding went to New Age projects concerning dolphin communications, dream research, altered states of consciousness, and the 1976 first edition of *A Course in Miracles,* among others.

The main focus of the EEF was transsexualism, at a time when little was known about trans people either among professionals or the public. The EEF granted hundreds of thousands of dollars in funding to most of the early researchers in the field, including the meetings of the Harry Benjamin Foundation, which, in turn, led to the EEF funding the June 20, 1966, opening of the first U.S. university-based gender clinic at Johns Hopkins and the second book ever written about transsexualism, Richard Green and John Money's (1969) *Transsexualism and Sex Reassignment,* as well as numerous other important research projects.

The EEF had offices open to the public in Baton Rouge, New York City, and Ojai, California. They maintained an extensive list of service providers throughout the United States and in several other locales, as well as took phone calls and office visits from trans people needing support and referrals. Funding was also provided to a number of the earliest trans peer support groups throughout the United States. At a time when information about trans people was almost nonexistent and nearly impossible to access, the EEF sponsored innumerable public addresses, educational films, radio and television appearances, and newspaper articles on trans topics directed at medical personnel, clergy, law enforcement, university and college students, and the general public. The EEF's projects also included an invaluable quarterly newsletter and a set of educational pamphlets that brought together information unavailable in any other way at that time. The value of these efforts for trans people and researchers alike would be hard to overstate.

One of the legacies of the EEF was its role in the origins of the World Professional Association for Transgender Health (WPATH). In July 1969, the EEF cosponsored the First International Symposium on Gender Identity with the Albany Trust in London, England. A second symposium in the series took place in Elsinore, Denmark, in September 1971, and the third was in Dubrovnik, Yugoslavia, in September 1973, both sponsored solely by the EEF. The 1975 and 1977 symposia were run by others and assisted by contributions from the EEF. When the EEF announced that it was closing, an emergency session to chart a way forward without the EEF was called at the February 1977 symposium. The formation of the Harry Benjamin International Gender Dysphoria Association, later renamed as WPATH, was approved at the February 1979 symposium in San Diego and officially incorporated in September of that year. WPATH counts these six conferences as their first.

The EEF's three main areas of work in the service of trans people—support and referral, advocacy and education, and research and professional development—led to significant and far-reaching improvements in the lives of trans people.

Ethnographies

As a research method invested in critically understanding social relationships in a range of geographic contexts, *ethnographies* provide one

productive avenue into the nuances of trans and other gender-diverse experiences around the world. The term *ethnographies* describes not only the qualitative research methodology, which involves semistructured interviews and participant observation, but also the written products that result from said research. As texts, trans ethnographies have proven foundational to the development of trans studies as a field. This entry provides context for the significance of trans ethnographies, including a brief historical overview, and reflects on the primary concerns, questions, and future directions of trans ethnographies.

Gender and Ethnography: A Brief History

Although ethnography was formally named a research method in the early 20th century as part of the development of the field of anthropology, the tenets central to ethnographies have been present in various historical writings. From travel writings to community-based oral histories, the practices of participating in community, observing and recording said observations, and interviewing community members have endured in a range of geographic areas and in many different populations, even though the products of such practices were not named "ethnographies." The emergence of ethnography as a formalized research practice is tied to a number of colonial projects. For example, scholars now considered foundational to the field of anthropology were enlisted by colonial governments to get to know, study, and draw conclusions about so-called primitive populations and their day-to-day lives. These early anthropologists (primarily white men) took detailed notes about everything about a given population: where and how they lived, what they cooked and ate, and who did the cooking, hunting, gathering, and other essential tasks to keep their community running. These divisions of labor were, in many cases, gendered, that is, determined along the lines of perceived bodily capacity based on a binary model of biological sex ("male" or "female"). Given the coloniality of these early ethnographies, such sex-based assumptions of "gender"—along with gender roles and gendered divisions of labor—were based on a Western, white, Euro-American model of gender that relied on a binary between femininity and masculinity.

As early as the 1930s, feminist anthropologists, quickly followed by lesbian, gay, and queer anthropologists, challenged the gendered assumptions of these early ethnographies by drawing attention to gender roles culturally constructed in ways that differed from this binary model. One oft-used example of such gender difference is the population now known as *two-spirit* in Native American communities. Initially called *berdaches* by European colonial officials and anthropologists who studied Mojave populations, anthropologists and other social scientists have long drawn on this third-gender (i.e., neither "male" nor "female," neither "man" nor "woman") population to exemplify the social construction of gender, gender roles, and sexuality. For anthropologists, two-spirit populations demonstrated the ways that "gender" can be defined not by biological sex but rather by occupation, social roles, and individual preference. For trans studies, as well as other studies of LGBTQIA+ communities, the existence and study of two-spirit populations have exemplified the transhistorical persistence of gender diversity. Some scholars, however, have cautioned against romanticizing the presence of two-spirit populations, noting the very real forms of violence and discrimination that these populations can face. Ethnographic methods, by attending to the on-the-ground realities for trans and gender-diverse populations around the world, can address these forms of violence as well as resistance and community building.

Contextualizing Trans Ethnographies

Along with ethnographies of two-spirit communities, ethnographies of other gender-diverse communities around the world—including *hijras* in India; *travestis, viado,* and *bicha* in Brazil; *māhū* in Polynesian cultures; *kathoey* in Thailand; *bissu, waria,* and *lesbi* in Indonesia; and trans communities in the United States—have come to perform symbolic work for Trans Studies. Ethnographies that situate these gender-diverse populations within their particular geographic, cultural, historical, and political contexts reveal the social construction of gender, as well as the existence and persistence of gender diversity. The social construction of gender, a tenet central not only to (trans)gender and sexuality studies but also to

notions of cultural relativism in anthropology, refers to the ways that gender, as a construct, is specific to the time and place within which it emerges. We can see this social construction quite clearly in the example of hijra communities in India: While hijras are culturally defined as neither men nor women, the gender system through which these communities define themselves is much more complex. Indeed, hijra identity—the subject of a great deal of ethnographic scholarship based in the South Asian subcontinent—is defined not only in relationship to sex and sexuality but also in terms of bodily practices, religious rituals, and caste status. Ethnographies of hijra communities take into account the particularity of each of these aspects in order to ascertain a robust picture of what hijra means to people on the ground. In so doing, these studies push scholarship from such fields as anthropology, sociology, and gender studies to attend to the nuances and specificities of gendered categories in any given cultural, geographic, and political context.

Trans ethnographies, then, can encompass not only those communities that may identify as trans or under a trans umbrella but also communities and populations that fall outside of binaristic, biological sex-based understandings of gender. While scholars disagree on whether or not "transgender" or "trans" can describe and hold the vast range of possibilities for gender difference, particularly outside of a U.S. or Western context, ethnographies play a productive role within Trans Studies. That is, ethnographies—texts that explore how gender has been constructed and understood within a given community, geographic context, institution, or population—allow Trans Studies scholars to see the expansiveness of gender difference on a global scale. Furthermore, these ethnographies help to underscore the transhistorical existence and persistence of communities who disrupt gender norms that rely on a white, Western binary between masculinity and femininity. By attending to such practices and characteristics as sexual acts, sexual labor, dress, roles in religious rituals, bodily modifications, and roles in community, these ethnographies reveal the variety of ways that gender can be experienced and defined.

Trans ethnographies may also include studies of communities inside the United States whose expression or experience of gender falls outside of a strict male–female binary, even if those communities do not identify as trans. Ethnographies tracing the work experiences, relationships, and identities of drag queens in New York City in the late 1960s and early 1970s, for example, are considered by some anthropologists to have set a precedent for trans (and queer) ethnographies. This ethnographic scholarship challenged normative assumptions of gender, sexuality, and labor by observing drag performances and interviewing drag performers (some deemed "street fairies" at the time) about how they made sense of the often-contradictory communities they built and traversed. Because many of these performers would have identified as cisgender, heterosexual men outside of the drag context, their presence within a trans ethnographies lineage is necessarily fraught. Indeed, the complexities and contentions of language use—more specifically, the use, circulation, and applicability of the category "transgender"—serve as a significant thread in trans ethnographies.

Language and Categories

Because the category "transgender," as numerous trans studies scholars have argued, emerged out of medical, academic, and social service institutions more so than out of communities on the ground, applying the language of "transgender" ethnographically—both within and outside of the United States—can be challenging for ethnographers. For many people of color, working-class people, and people without access to institutionalized language in the United States, and for many people outside the United States, the category "transgender" is unfamiliar or inaccessible. For this reason, language complicates trans ethnographies, methodologically and theoretically: Some anthropologists, for example, have described their difficulty approaching communities that social service agencies may call "transgender" but who may not identify as such themselves. Methodologically, ethnographers may find it difficult to recruit and determine research subjects, who may use such terms as *gay* or *woman,* but not *transgender,* to describe themselves.

By attending to such complexities of gender categories and language use, trans ethnographies can work to unsettle gendered assumptions in a

structural way. These questions of translation, circulation, and identification in language use—that is, how different gendered categories translate across linguistic barriers, circulate in a variety of institutional and community contexts, and become taken up as identity categories by a range of people—are central to trans ethnographies at both the research and writing stages. When ethnographers build relationships with, interview, and observe their interlocutors, for example, they may consider including a range of subjects, who may or may not identify as "trans" but who may have a critical or nonnormative relationship to their gender expression. Finding and developing a rapport with these subjects—a crucial stage in the process of conducting ethnographic research, which for many occurs prior to the actual collection of ethnographic data—often means adding an extra step of learning the gender system(s) embedded in different communities. This is as true in transnational research that works across linguistic barriers and geographical distance as it is in research on various communities in the United States with distinct and complex gender systems. One prominent example is ball culture, which has persisted in Black LGBTQIA+ communities from at least the 1920s to the present in many cities in the United States: A range of categories, including "butch queen," "femme queen," and "butch" (each with its own set of rules and expectations that sit outside of a white, hetero- and gender-normative gender system), structure the competitions and communities for ball participants.

The (linguistic) complexity of culturally specific and community-based sex/gender systems is thus one prominent thread in trans ethnographies. By beginning with the presumption that the construction of gender coheres differently depending upon the context, trans ethnographies unsettle assumptions about gendered categories *and* expand the possibilities for research topics and subjects. When taken to include a range of gendered categories, experiences, and roles that extend beyond the category "transgender," trans ethnographies open these possibilities for Trans Studies as a field. Furthermore, by taking this capacious approach to gender and gendered language, trans ethnographies require that Trans Studies as a field remain critical of the ways in which the category "transgender" persists primarily in Western or U.S.-based institutions. This institutionalization necessarily limits the kinds of access that different communities (within and outside of the United States) have to the category itself and the language that surrounds it: Trans ethnographies, then, place important pressure on Trans Studies as a field to remain accountable to communities on the ground.

One recent trend in Trans Studies has been for scholars to include personal reflections. Along with trans memoirs, which trans communities have long used as a platform to share and analyze personal experiences, such scholarship might be considered autoethnographic. Autoethnography, considered a subset of ethnographies, describes participant observation of and critical reflection on personal experiences. In Trans Studies, these critical reflections help to buttress scholarly claims about the complexities of navigating everyday life as a trans person. From meeting with doctors to discuss options for surgery and hormones to navigating a range of security and surveillance systems in the United States, trans scholars have included their personal experiences in their scholarship in generative ways. As with trans ethnographies more broadly, the inclusion of autoethnographic writing has pushed the field of Trans Studies to attend to on-the-ground, everyday realities for trans people.

Future Directions

Further research in Trans Studies that uses ethnographic methodologies should continue to take care in attending to the specificities of different geographic and cultural contexts to address the issues outlined in this entry. Ensuring the participation of diverse communities in ethnographic studies and recognizing the complexities of language will continue to be crucial for all ethnographic research, specifically trans ethnographies, which grapple with gender and sexual diversity in numerous geographic and cultural contexts. Furthermore, given the colonial histories of ethnography, the position of ethnographer is very often one of (even relative) privilege, and ethnographers—of any gender identity—should continue to attend to the specificity of their subject position. By

critically centralizing the diversity within trans communities, including the forms of power *and* privilege, trans ethnographies will continue to shape the ways Trans Studies speaks to and with communities on the ground.

F

Fa'afafines

Fa'afafine (pronounced fa-a-fafee-nay) is a culturally specific term in Samoan, a language spoken by the indigenous Polynesian people of the Samoan islands, referring to those with a specific nonbinary gender identity. The term *fa'afafine* is composed of *fa'a,* meaning "in the manner of," and *fafine,* meaning "woman." Fa'afafine refers to people whose sex assigned at birth is male and whose gendered behaviors are feminine or women-like. The majority of fa'afafines present with a feminine gender expression and behave in ways that are consistent with traditionally female social roles. However, there is variation among how each fa'afafine understands and expresses their gender identity. Some fa'afafines understand their gender identity as being not just feminine but of being both masculine and feminine. This entry explores the experiences of fa'afafines in Samoa, including their role within Samoan society, embodiment of gender expressions within this identity, and the recognition of the fa'afafines' identity.

Social Roles

According to research with this population, fa'afafines become aware of their preferential interest toward femininity at a young age. Because this gender identity has a degree of social acceptance in Samoan culture, many families will support and raise their children as fa'afafine. In comparison to the emphasis on individualism in Western societies, social roles in Samoan culture are based in collectivism and thus are associated with how members of the community can benefit those around them and the communities they belong to. The social roles for Samoan children are focused on assisting the family unit with household-related chores. In general, within this culture, young men tend to take on more physically labor-intensive tasks that occur outside the home (e.g., providing food and shelter), whereas young women take on tasks inside the home, which are related to caretaking and nurturing (e.g., washing, cleaning, cooking, childrearing). Fa'afafines are likely to engage more in stereotypically female social tasks and behaviors from childhood, which is often encouraged by families. In adulthood, many fa'afafines extend their caretaking roles by taking care of their elderly parents or assisting in childrearing, either for their own children or children of siblings and other family members.

Embodiment

While fa'afafine is an accepted identity within Samoan culture, individuals with this identity embody it in a variety of ways. In terms of social forms of gender expression such as dress and makeup, some fa'afafines may wear a *puletasi,* the traditional Samoan two-piece women's outfit, and may assume the women's roles during the *taualuga,* a Samoan traditional dance form. Some fa'afafines present themselves in a remarkably

feminine manner, including makeup, jewelry, feminine hairstyle and attire, and feminine-pitched voice. These efforts may result in being able to publicly "pass" as female. Other fa'afafines may choose to present themselves with a milder feminine presentation such as occasionally wearing nail polish and using feminine hand gestures. Embodiment of the identity may change over time; for example, some fa'afafines may choose to present themselves in a feminine way daily, only on few occasions, or in between these two limits. Some fa'afafines may also prefer to present with an androgynous or masculine gender presentation.

In addition to clothing and makeup, some fa'afafines may elect to undergo gender affirmation surgeries and hormone treatments to express their gender. However, it is rarer than it is in the United States for fa'afafines to elect such surgeries and treatments. For individuals who undergo gender affirmation surgeries, they often continue to identify as fa'afafine and not as a woman due to connection they have developed with the fa'afafine community. Alternatively, not all fa'afafines choose to reduce the physical characteristics that are part and parcel of male biological processes (e.g., shaving facial hair).

While fa'afafine is a gender identity, not a sexual identity, the majority of fa'afafines self-identify as being attracted to masculine-presenting, cisgender, heterosexual-identified men. Within Samoan culture, it is not uncommon for cisgender, heterosexual men to have intimate relationships with fa'afafine partners. However, more research needs to be conducted to explore whether these practices are accepted by the society generally. These relationships are facilitated by the cultural and social awareness of fa'afafines and the recognition that, unlike in heterosexual pairings, sexual exploration with fa'afafines does not result in unwanted pregnancies. Overall, it is important that the conceptualization of sexual orientation and gender identity categories in Western societies not be generalized to Samoan culture.

Identity Recognition

The fa'afafine identity is widely recognized in Samoa. A popular form of entertainment and cultural celebration are fa'afafine pageants, which are held in Samoa multiple times a year and are attended by local Samoans and tourists. Pageants are a place for fa'afafines to publicly display their femininity and allow fa'afafines to continue to hold awareness of their role in Samoan society and culture. Yearly pageants are organized by the Samoa Fa'fafine Association (SFA), a nonprofit organization that promotes fa'afafine rights and interests in Samoa. The pageant-generated funds are used to help support them in their advocacy work.

The fa'afafine community is tolerated and mildly accepted by the Samoan society. Even though the community is recognized, fa'afafines still experience different forms of institutional and interpersonal discrimination. Organizations such as the SFA work to advocate for equal legal rights (i.e., recognition of same-sex marriage) and laws that protect the fa'afafine community from discrimination in Samoa. There is additional need for further research on the experiences of fa'afafines who also hold other marginalized identities (e.g., low socioeconomic status) to better understand the variance in how they are perceived and treated within Samoa.

Families: Transnational and Global Perspectives

This entry explores ways that trans and gender-diverse people create and sustain families and navigate family pressures, with a focus on transnational and global contexts that are underrepresented in transgender family studies. Definitions of family, like definitions and expressions of gender, are numerous and fluid. Scholars have long recognized the importance of chosen family and fictive kin—family relations that are not based on blood or marriage—among LGBTQ+ communities, Black American communities, recent immigrants to the United States, and other groups. More heteronormative models of family are also culture and context specific. For example, in some cultures, grandparents, aunts, uncles, and cousins are a part of the core family, while in other cultures and contexts, these relationships are considered more distant or "extended." Some societies distinguish legally and/or culturally between paternal and maternal relatives and in-laws, while others do not. Thus, the very definition of family in a study of trans family relationships may harbor cultural (usually white North American) biases. This entry uses a subjective definition of family, inclusive of the relationships that trans and gender-diverse people themselves consider to be family within transnational and global research on this topic. It is certainly possible that researchers have missed aspects of trans family life because of their/our cultural and personal definitions and lenses. This is an area for continued exploration and critical reflection as scholars expand the scope of transgender family studies.

Strengths of Trans Family Ties

There are many examples, drawn from nearly every continent, of ways that trans people create and sustain kinship and family ties. Often these ties are with other trans and gender-diverse individuals, as in *khwajasara/hijra* households in Pakistan and India, coresidence with trans siblings and mother/father figures in Peru, "families of choice" among trans Latinx immigrants to the United States, and other transnational and global contexts. In some South Asian and indigenous communities, gender-diverse people have specific community roles that involve caring for children and performing other family labor.

These families of choice and communities of care may stand in for families of origin that have abused and/or expelled their trans members. As such, they serve crucial and lifesaving roles, particularly as many societies allocate the burden of social security to families. However, families of origin are not uniformly rejecting. The global body of research on transgender people and their families points to high levels of family cohesion as well. For example, trans people having origins in the Pacific Islands report very close family ties compared with nonnative groups in the region. The assumption that families of origin are inherently hostile to gender diversity obscures the tenderness and resilience that is also present for many.

Family Pressures

Family pressures on trans and gender-diverse people vary socially and culturally. The reasons why a parent or grandparent may embrace or reject a transgender child, for instance, reflect the social and cultural resources available to them. Some may be religiously motivated, while others are more concerned about posterity or other core values. Pressures around heterosexual marriage and reproduction are widely reported. Studies conducted in China, Hungary, India, Indonesia, Iran, Japan, Pakistan, Taiwan, and Turkey, among many other places, show marriage compliance to be among the primary concerns for families of origin. That is to say, trans people are under enormous pressure to marry, have children, and care for the younger and elder generations in a "traditional" family arrangement (and, of course, what is traditional will also vary from place to place). Trans

people have found creative ways to manage such pressure. Some enter marriages that appear to be traditionally gendered and heterosexual (in accordance with sex assigned at birth) to appease their families and/or as a protective cover. Many people maintain close relationships with kin through strategic silences. Others choose to disclose that they are trans in order to resist marriage or, conversely, to access heterosexual marriage through social and legal gender transition.

A common thread in accounts of trans kinship and family is the inability, or refusal, to break away from the family of origin. In many places, leaving one's family is simply not socially or economically feasible, nor is it desirable to significant numbers of trans people who remain deeply embedded in kinship and family networks. Thus, family-of-origin relationships continue to be worked out in intimate daily living and often in coresidence. Support for trans people must take these family arrangements into account. Similarly, support for family members of trans people—such as parents, grandparents, siblings, cousins, spouses, and children—must consider the contexts in which they live and structure their relationships.

A third theme arising in numerous studies is the gendered division of family labor, encompassing housework, childcare, eldercare, care for ancestors, emotional labor, and other paid and unpaid work. Family work is used both to suppress trans people, ascribing roles and responsibilities rigidly based on sex assigned at birth, and to affirm trans people by allowing them the flexibility to reconstitute roles and responsibilities according to their genders and in ways that signal their genders to others. As a majority of societies remain highly gendered and patriarchal in family organization, these are aspects of transgender family life that must be considered.

Transnational Family Relationships

Family relationships often spread across countries and continents, and this, too, shapes the family experiences of trans and gender-diverse people. Family can serve as both a push-and-pull factor in transgender migration trajectories. Some trans people migrate to create families, to provide for their families, and/or to reunite with loved ones. Others migrate to put distance between themselves and a family that is hostile to their trans personhood. Family issues intersect with other reasons for migration, such as departure from violence and poverty. For significant numbers of trans migrants and asylum seekers, this includes violence inflicted by family members and poverty exacerbated by the withdrawal of family support.

Migration processes bring people into contact with the power and surveillance apparatuses of multiple nation-states. Possibilities for mistreatment and abuse are compounded by the variety of ways that states determine a person's legal gender and enforce binary gender categories, often under the guise of national security. This holds implications for family life as well. For example, trans people face barriers to common pathways to immigration and naturalization through spousal and family relationships. The validity of a marriage for the purpose of immigration relies upon sex assigned at birth in most of the world. Even as some countries provisionally open a door to trans recognition and/or to same-sex marriage migrants, discrepancies among legal documents—such as a change in one's sex marker—can result in more scrutiny and even denial of one's application under xenophobic immigration systems like the one currently in place in the United States.

Family is a crucial site of struggle in movements for trans liberation and immigration justice. Immigrants and LGBTQ+ people are co-constructed as threats to "the family" in nationalist and nativist rhetoric worldwide. Trans migrants and their loved ones are among those exposing the flaws and violence of this rhetoric. Some trans and queer groups have called for a radical restructuring of the U.S. family immigration system. These groups reject trans and queer assimilation into the existing system and advocate instead for state recognition of the much broader definitions of family that exist in people's lives. As some scholars have pointed out, more expansive and thus more accurate understandings of "gender" and "family" are urgently needed in immigration politics as in other social institutions.

Knowledge and Power in Transgender Family Studies

Transgender family relationships—and theories about these relationships—reflect the ways that knowledge and power operate on a global scale.

Colonialism and settler colonialism, such as the ongoing occupation of Indigenous lands in the Americas, have ravaged Indigenous kinship and family structures in ways that have deep and enduring effects on trans and gender-diverse people. For example, Europeans violently suppressed nonbinary genders and more flexible sexual and social roles in parts of the world that they took by force. Norms and laws put in place by colonial regimes pathologized and criminalized people who did not conform to European, Judeo-Christian understandings of gender and family. These are not only historical legacies but also ongoing acts of violence and erasure, as Indigenous communities around the world continue to experience occupation of unceded lands.

At the same time, funding for research and organizing, journal article and book publishing, and other resources for trans communities continue to be dominated by more affluent, English-speaking countries. Organizations and individuals who need these resources are often pushed to frame their stories in ways that the dominant groups recognize and value. Eurocentric models of transgender identity and family are used as the reference point for discourses, policies, services, and other resources that circulate globally, having real, material impacts on gender-diverse people and their loved ones. Going forward, it is imperative that scholars and students ground their work in anticolonial, decolonial, Indigenous, transnational, and global perspectives. Such grounding will enable advocacy and other work stemming from this knowledge to meet the needs of greater numbers of trans and gender-diverse people, as well as to inform more inclusive and thus stronger theories of gender and family ties.

Family Therapy, Trans Youth

Trans youth enter counseling for a variety of reasons, including their need to sort out and clarify their own understanding of their gender, manage and reduce distress that arises internally or as a result of harassment or rejection by others, improve their communication to significant others about their gender, and/or gain access to medical

transition steps. Therapy may be initiated at the youth's request or by their parents or guardians. This entry explains why family therapy is an essential component of mental health care and advocacy for trans youth and describes some of the components of family therapy specifically for trans youth.

Family therapy is essential for trans youth for a number of reasons. Trans youth often lack support from their parents. Most parents are unprepared to guide their youth in gender exploration. Some families are openly hostile to their child's assertion of a trans identity. Family therapy reduces or eliminates rejection and helps parents appropriately support their youth, leading to the most favorable outcome for the young person.

Children who suffer harassment or discrimination based on race, religion, or socioeconomic status generally have parents who have experienced the same challenges. They get validation from their family for who they are despite the negative views that may exist in their community. They receive guidance about how to respond safely to harassment and support to counter anguish and rage when not feeling safe to respond. This helps them develop self-esteem even in the face of disrespect from others.

Most trans youth do not have parents or any extended family members who are trans. As with other youth whose stigmatized status is not shared by their family, their parents are not able to offer an insider's view on how to cope with these challenges. Parents, in fact, often feel completely unprepared to offer the support and guidance these children need. And many families are initially quite rejecting of their trans young people.

Research has demonstrated that family rejection of trans youth leads to a higher risk of low self-esteem, mental health problems, and suicide attempts. In addition, success in social and medical transition is highly dependent on parental support. For these reasons, family therapy has an extremely important role in the assistance offered to trans youth. Family therapy is a vehicle for altering rejecting behaviors as well as a way to help parents understand and advocate for their children. Many of the steps that trans or questioning teens need to take require parental agreement. Other steps for teens, as well as those for young adults, may be accessed without parental support but require greater effort and forbearance in the absence of family support. Some trans youth not only lack active parental involvement but have also been rejected subtly or directly by their family for being gender nonconforming or trans. They carry a heavy burden that weighs them down in the process of self-actualization and impedes their progress. For these young people, family therapy is key if it is at all possible.

Family therapy begins with the young person's drive to embrace and express their authentic self and the parents' determination to proceed safely. Many youth arrive to therapy feeling they already know exactly who they are and what they need. They are often well informed about trans identities and the relevant medical interventions. They are impatient to proceed. Parents are often shocked and confused. They have generally had little time to process this new information, while their child has been mulling it over for months or years before telling them. Parents may have trouble believing that what their child is saying could be true. They fear for their child's safety. The family therapist needs to understand and validate both the youth's urge for authenticity and the parents' fears for their child's safety.

The goals of family therapy are to improve communication and understanding, as well as to examine the urge for an authentic life and the safety concerns that arise with gender transition, while keeping in mind any risks from not transitioning. Family therapy is likely to include the following:

- Individual sessions for the young person to establish rapport and gain a full understanding of the youth's gender identity, any related harassment or distress, any mental health or substance abuse concerns, and any transition goals
- Sessions for the parents or guardians to establish rapport, provide a general education about gender identity, and examine and address parents' fears and concerns about their youth's trans identity and desired transition steps, with attention to relevant cultural, racial, ethnic, religious, or socioeconomic factors affecting the parents' concerns
- Referral for ancillary mental health or substance abuse treatment, if needed
- Conjoint sessions with the youth and parents or guardians together to provide an opportunity for the youth to share their gender history, any related harassment or distress, their current understanding of their gender identity, and desired transition steps

- Inclusion of other significant family members as indicated
- Contact with school or other care providers as warranted
- Identifying additional supports for the youth and family, such as support groups and conferences, as well as books and information or support available online

By paying attention to both authenticity and safety, it is usually possible to reach a shared understanding between the youth, the parents, and the therapist that guides any decisions moving forward. Family therapy continues through the process of the youth and family implementing social and medical transition steps, often shifting to less frequent sessions over time. As families gain confidence and make connections to supports in their community, ideally including other families going through this process, their need for help from a mental health clinician diminishes. Family therapy remains a resource they can call on as needed.

Feinberg, Leslie

Leslie Feinberg (1949–2014) was a revolutionary communist, pioneering trans warrior, social justice activist, and trailblazing author, historian, theorist, and intellectual. Feinberg self-identified as an antiracist, white, secular Jewish, working-class, transgender, butch lesbian female. Feinberg was the first to advance a Marxist theory of "transgender liberation" in a pamphlet of the same name and subtitled *A Movement Whose Time Has Come*. Feinberg authored a world-renowned novel, *Stone Butch Blues,* and the first history book about trans people, *Transgender Warriors,* in which ze popularized "transgender" as an umbrella term for all individuals who were gender nonconforming.

Early Years

Born in Kansas City, Missouri, on September 1, 1949, Feinberg grew up in Buffalo, New York, in a working-class, Jewish family. Assigned female at birth, Feinberg said that people saw hir gender expression as male. Hir parents were hostile to hir gender identity, which led hir to move out at age 14 and start working in a local department store. Eventually, ze stopped attending high school and began to explore the queer social scene in Buffalo gay bars. Bennett High School still awarded Feinberg a diploma.

Feinberg went on, through self-education, to gain extensive knowledge about international history, sexes, gender identities, and sexualities within the context of nationalities and class. Starr King School for the Ministry awarded Feinberg an honorary doctorate for hir transgender and social justice work.

Career and Activism

Discrimination against hir as a trans person made it impossible for Feinberg to get steady work in the

late 1960s and 1970s, so ze moved from one low-wage temp job to another. When Feinberg was in hir early 20s, ze joined the Workers World Party (WWP). After moving to New York City, ze helped organize numerous antiracist, antiwar, and prolabor protests for the WWP. Feinberg served as editor of the Political Prisoners page of *Workers World* newspaper for 15 years, and in 1995, ze became managing editor. Feinberg was a member of the National Committee of the Party, the National Writers Union, United Auto Workers Local 1981, and Pride at Work, an AFL-CIO constituency group.

Feinberg developed hir writing skills and wrote prolifically on socialism and LGBTQ history in a column, "Lavender & Red," featured in 120 issues of *Workers World,* from 2004 to 2008. A selection from the series became Feinberg's final book. Published in 2009, *Rainbow Solidarity in Defense of Cuba* documents revolutionary Cuba's liberation of sexualities, genders, and sexes.

Feinberg wrote in multiple genres: fiction, history, theory, and journalism. Feinberg was the first theorist to advance a Marxist concept of "transgender liberation," and hir work affected popular culture, academic research, and political organizing. Feinberg authored the first comprehensive book on trans history, *Transgender Warriors: Making History From Joan of Arc to Dennis Rodman.* In *Transgender Warriors,* Feinberg (1996) defines *transgender* as a broad umbrella term, including "everyone who challenges the boundaries of sex and gender" (p. x). Feinberg's writing has been widely anthologized and taught in U.S. colleges and internationally. Hir biggest impact on popular culture was through hir 1993 first novel, *Stone Butch Blues,* which enabled readers to identify with the experiences of a trans person who faced brutal oppression from society but who found solidarity with others to emerge whole. Sold in hundreds of thousands of copies and eventually placed online as a free download, *Stone Butch Blues* has been translated into Chinese, Dutch, German, Italian, Turkish, Slovenian, and Hebrew.

Personal Life

Feinberg met poet and activist Minnie Bruce Pratt in 1992 in Washington, D.C. when Feinberg presented hir research on figures in trans history. After a long-distance courtship, the couple made their home for many years in Jersey City, New Jersey. They became domestic partners in 2004 and had a civil union ceremony in 2006. They were married in 2011, after same-sex marriage became legal in parts of the United States.

Awards and Recognitions

Feinberg received many awards and recognitions. *Curve* magazine named hir among the 15 most influential people in the battle for LGBTQ rights. Feinberg also won the American Library Association's Stonewall Book Award for Literature and the Lambda Literary Award for a Small Press Book in 1994 for *Stone Butch Blues* and the Firecracker Alternative Book Award for nonfiction in 1997 for *Transgender Warriors*. In 2015, The Trans 100 list honored Feinberg posthumously as one of the most influential trans people in the United States. In 2019, ze was among the inaugural 50 American "pioneers, trailblazers, and heroes" named on the National LGBTQ Wall of Honor within the Stonewall National Monument in New York City.

Illness and Death

Feinberg died at home in Syracuse, New York, on November 15, 2014, at age 65. Diagnosed in 2008 with Lyme disease and multiple tick-borne coinfections, Feinberg had first been infected in the early 1970s when little was known about the disease. Ze received treatment only within the last 6 years of hir life. Feinberg attributed hir catastrophic health crisis to bigotry and prejudice, as well as discrimination against trans people that made access to quality health care difficult.

In hir final days, Feinberg worked on a free, online version of *Stone Butch Blues*. This edition includes a slideshow Feinberg created, "This Is What Solidarity Looks Like," which documents the struggle to free CeCe McDonald, a young Black trans woman who was imprisoned for defending herself against a white, neo-Nazi attacker. Feinberg dedicated the online edition to McDonald and was arrested for painting "Free CeCe!" on the wall of the prison that held McDonald. Feinberg's last words were, "Remember me as a revolutionary communist."

Lasting Legacy

Feinberg's writings and activism significantly contributed to the growth of the trans community and the trans equality movement. Ze repeatedly pointed out that trans people were leaders and at the forefront of the Stonewall Riots and other acts of resistance that led to the modern LGBTQ+ movement. Feinberg's personal research library, including more than 1,500 books, periodicals, political pamphlets, and academic papers, is housed at the Sexual Minorities Archives in Holyoke, Massachusetts.

Femininities and Femme

Feminine multiplicities have always existed. Within recent years in particular, LGBTQIA+ communities have witnessed the proliferation of queer femininities. Yet, there is a gap in academic attention such that far less attention has been paid to the diversity of feminine embodiments. This entry explores some of these queer femininities and feminine identities, particularly the concept and history of *femme*. As will be discussed, femme challenges the norms of femininity and womanhood, making it particularly relevant for trans and queer communities alike. Importantly, this entry explores identities specifically related to femininity (gender) and distinct from woman (gender/sex) or sex (female).

Femme History

The origin of femme can be placed within 1950s North American lesbian communities. Here, femme referred to feminine lesbians within a butch–femme relationship. Many femme scholars have since critiqued the way this operationalization of femme hinges on the definition of femme exclusively in relation to butch. Within this context, *butch* referred to the masculine partner who was often designated as gender nonconforming and thus seen as more "authentically" lesbian. Fore-femmes and contemporary femmes alike have taken issue with notions of sexual authenticity and can be critical of the idea of gender nonconforming altogether, given how this concept does not capture the multiple ways that gender can be transgressed. Although, historically, femmes were often invisible, and their queerness subsumed under an ostensible normality, femmes have always been and continue to be a radical form of femininity. In fact, femme and butch lesbians were both included among the trans umbrella within foundational trans scholarship, such as Leslie Feinberg's 1996 text *Transgender Warriors*. With an increasingly nuanced understanding of gender, sex, and gender/sex, femme and butch are no longer seen as inherently existing exclusively under a trans umbrella. Rather, femme, like butch, can be cis or trans.

Femme Today

Today, femme has come to mean many things to many people, and at times, this multiplicity can cause some discord among those for whom femme resonates. Branching in some ways from the original meaning of femme, contemporary scholarship highlights the multiplicities of femme that expand beyond cis feminine lesbians, including, but not limited to, women and men, whether trans or cis, and nonbinary folks of all sexual orientations. Theorizing the multiple invocations, Rhea Ashley

Hoskin's (2017) "Femme Theory" postulates femme as deviations from patriarchal norms of femininity, norms that dictate "who" can be feminine and "how." For instance, patriarchal femininity normalizes whiteness as feminine, alongside being assigned female at birth, heterosexual, able-bodied, thin, and walking the tightrope of feminine sexuality (i.e., appearing sexually available but not sexually desiring). Femme bares particular relevance for trans and queer communities because the term is often adopted as an identity that subverts expectations about how women should look, behave, or identify. Thus, according to femme theory, *femme* refers to challenging or doing away with the prescribed norms of femininity. In essence, femme questions the assumptions made about femininity, as well as who is "allowed" to be femme and "how." In this questioning, femme highlights the tendency for femininity to be more heavily policed than masculinity (e.g., femmephobia) and how masculinity tends to masquerade as "gender neutral" or androgynous.

Queer Femininities

Many queer femininities could be considered as falling under the umbrella of *femme* as it is defined by femme theory. Included among these multiple femme identities is trans femme and nonbinary femme. Perhaps as a result of the insufficient academic attention paid to femme and femininities, many identity labels are used functionally within the context of LGBTQIA+ communities but do not fully coalesce into a universal meaning or definition, or the meanings attached are fluid and contextually different. For example, terms such as *transfemme, trans femme, trans feminine, trans fem, femme-of-center, feminine-of-center, high femme, soft femme, low femme, futch, butchy femme, tomboy femme,* or *twink* carry meanings that can shift depending on the person, the context, or the subculture.

While meanings can and do shift, some of these terms carry central tenets of meaning. For example, *transfeminine* or *trans-feminine* are umbrella terms but can also refer to an identity or gender expression held by trans people, typically assigned male at birth, who identify with femininity to a greater extent than masculinity. This can include trans women, nonbinary people, or gender-fluid people. To some people, the term *nonbinary femme* may seem contradictory or confusing. While some nonbinary individuals, such as neutrois, identify as neither female/male or feminine/masculine, others identify themselves as leaning more toward one side of the gender binary or moving across. Transfeminine people and nonbinary femmes can be examples of a nonbinary identity that leans toward the feminine side of the spectrum. *Transfeminine spectrum* typically refers to those assigned male who move either in the direction of feminine (note: female and feminine are not the same thing). This term is a way of making feminine gender expression salient, independent of being a woman, while also leaving space and acknowledging the capacity for trans women to express in a multitude of ways, such as masculine, androgynous, or agender.

Feminism

In the United States, feminist history is usually categorized in "waves" (first, second, and third), each characterized by its own goals and priorities. The wave metaphor, however, obscures the diversity of feminist thought and politics, as well

as the range of competing feminist perspectives on many topics, including trans people. While feminism and trans liberation may seem like natural allies, sharing a commitment to gender equality, their relationship is somewhat fraught. Since the 1970s, feminists have asked various versions of the "transgender question," positing whether trans people are "good" for feminism or advance its goals. These debates have major consequences for trans people within and outside of the feminist movement. Trans people, in part through the development of transfeminism, assert their own theories of gender and inequality, carving out multiple visions of trans liberation that both converge with and depart from other feminists.

Constructing the "Transgender Question"

In the 1960s and early 1970s, before the rise of trans exclusionary radical feminism, trans people participated in feminist organizing without much fanfare. A small group of radical feminists and lesbian separatists believed that trans women were "really men" and inherently antifeminist. Several altercations in 1973, however, amplified these perspectives in the broader community. During Christopher Street Liberation Day (a precursor to gay pride), lesbian activist Jean O'Leary accused drag queens and trans performers of exploiting women through their art—trans activists Sylvia Rivera and Lee Brewster interrupted her mid-speech. That same year, at the West Coast Lesbian Conference, musician, lesbian organizer, and trans woman Beth Elliott was set to perform when a keynote speaker denounced her as a male infiltrator and likely rapist. Later, in 1979, Janice Raymond published *The Transsexual Empire: The Making of the She-Male,* a feminist anti-transgender manifesto influential within and outside feminist movements. It has been used to mobilize and legitimize much violence against trans women.

For Raymond and her peers, feminism must center women's experiences. But this premise fails to account for the fact that women—even cisgender (cis), or non-trans women—do not share a singular experience. Black feminists and trans feminists, among others, argue that the notion of universal womanhood only centers more privileged women. Some groups even align under the identity "womxn," which aims to reclaim womanhood from its associations with both whiteness and cis-ness. Moreover, although trans exclusion has come to characterize "second-wave" 1970s feminism, there have always been acts of resistance and support for trans people.

This ambiguity around gender categories also characterizes the butch/FTM (female-to-male) border wars, which erupted in the 1990s, resulting in various forms of intercommunity conflict. Although many trans men once belonged to feminist communities and identified as lesbians, some felt the need to denounce these connections to be taken seriously as men. Meanwhile, many butch lesbians struggled to defend their masculinity as a legitimate expression of womanhood—and to distinguish themselves from trans men. The butch/FTM border wars were fundamentally about the question of who could be involved in lesbian feminist community/politics, which is another way of asking the transgender question. Tensions led some radical feminists to dismiss trans men as self-hating lesbians and to harass their former peers, posttransition. Other feminists, however, want to destigmatize the overlap between these two gender categories and to create more room for exploration without judgment.

Another important shift in the 1990s involves the rise of poststructural feminism and queer theory, particularly the work of Judith Butler. Literatures grounded in these theories discuss trans people and trans bodies in order to argue that neither gender nor "biological sex" exist outside of cultural contexts or understandings and the systems of knowledge that produce them. This is a significant departure from trans exclusionary radical feminism. Butler, for example, claims that queer and trans expressions of gender denaturalize rigid gender norms and thus can promote a feminist agenda. Some trans scholars, however, treat Butler and poststructural theory with skepticism. While breaking from anti-trans discourse, poststructuralism still accepts the basic premise of the transgender question, debating—for example—whether trans people are "good" or "bad" for feminism or whether they reinforce or transcend binary gender norms.

Trans Scholars Rebuke the "Transgender Question"

If feminism intends to improve people's lives, then we must examine its actual impact on trans

communities. Scholars Viviane Namaste and Raewyn Connell discuss how most feminist theorizing on trans issues privileges a mainstream feminist agenda (*what is gender and how does it work*) over addressing trans people's needs. Namaste focuses on the work of Judith Butler, whose theories dominate contemporary feminist thought. Although Butler examines violence against trans women, she does so through the lens of anti-trans prejudice. But most violence against trans women, Namaste counters, occurs because of their disproportionate participation in sex work—which Butler ignores. Feminist theory and politics, she argues, must consider the specificity of trans lives.

The problem with poststructuralism, Connell contends, is that it only engages with *some* dimensions of gender, thus limiting what it can tell us about trans individuals. For example, common themes in feminist texts include the self, subjectivity, discourse, categories, and representation. Such scholarship is not inaccurate, but it does not capture the fullness of trans experience. Connell argues that feminist scholars should also consider the constellation of economic, political, and social relations that constrain trans people's lives. Furthermore, she and Namaste reject the notion of a transgender question that excludes trans people and trans perspectives from the production of feminist knowledge.

U.S. Transfeminisms

Trans women have likely existed in and beside (trans)feminist movements for as long as they have existed. For example, in the 1970s, trans women Beth Elliott, Sylvia Rivera, Sandy Stone, and Marsha P. Johnson laid the foundations for what would later be named "transfeminisms." But it was the publication of several key texts in the early to mid-2000s, however, that drew significant public attention to U.S. transfeminism as both a theory and practice. In *Whipping Girl,* Julia Serano provides trans women with a common language to understand their oppression as distinct from but related to misogyny/sexism and transphobia/trans-antagonism, coining the term *transmisogyny.* Meanwhile, in "The Transfeminist Manifesto," Emi Koyama popularizes the term *transfeminism* by expanding the discussion of feminist topics to include the needs and desires of trans women. For example, she notes similarities between how trans women and cisgender women experience body image, violence, and attacks on bodily autonomy.

Both texts have been critiqued for marginalizing the experiences of trans people of color, working-class trans people, and trans men, among others. Some critics believe these texts are also limited by their reliance on a neoliberal rights-based argument for liberation. The neoliberalization of social movements in the United States is articulated in Lisa Duggan's *The Twilight of Equality?* while the rights-based manifestation of trans politics is explained by Dean Spade in *Normal Life*. But to summarize, "The Transfeminist Manifesto" and *Whipping Girl* understand the liberation of trans women as only related to the oppression of cis women, invisibilizing the effects that racism, classism, and ableism have on the lives of trans women who are not white, wealthy, able-bodied, and so on. In addition, these texts offer a narrow view of trans liberation, linking trans women's freedom to public acceptance/tolerance rather than the dismantling of social inequalities.

Like all men, trans men benefit from patriarchy and can be sexist and trans-misogynistic; to feel legitimized as "real men" and to avoid violence, trans men may feel called upon to perform hyper or toxic masculinities. At the same time, trans men also contribute to transfeminist knowledge and practice. For example, scholars like Henry Rubin and Jacob Hale encourage trans men to act in solidarity with women—particularly trans women—and nonbinary trans people. They call on trans men to reflect on how they participate in patriarchy and to interrogate their relationship to masculinity. Masculinity is not necessarily harmful and can be an important aspect of someone's identity, but it can also be weaponized against people of all genders and used to justify harmful behaviors. While difficult, remaking masculinity is a key part of gender liberation and involves both personal and collective transformations.

Global Transfeminisms

Trans feminists outside the United States have also played substantial roles in (re)defining what transfeminism can mean. For example, global trans feminists argue for a decentralization of the West and the English language, against police brutality

of trans sex workers, for de/anticolonialism, and for a movement inclusive of all marginalized people typically excluded from mainstream LGBTQ, feminist, and women's movements. Some people draw from Anglo-American trans feminists, some from Indigenous knowledges of transfemininities, and some from arguments against local mainstream social movements.

Various authors have argued that we need a transnational, pangender, and antiracist transfeminism invested in massive wealth redistribution. Nat Raha, based in Scotland, articulates one pathway forward via Radical Transfeminism. Radical Transfeminism is a movement that centers a commitment to countering the systems of oppression that harm transfeminine bodies globally. Another possibility was presented in 2009 in Granada, Spain, in a statement titled the *Manifiesto para la Insurrección Transfeminista* (*Manifesto for Transfeminist Insurrection*), which argues for a more expansive feminism, inclusive of "the dykes, the whores, the trans, the immigrants, the blacks, the hetero dissidents." A commitment to transfeminism means a commitment to mitigating violence against trans people around the globe, both in and beyond gender oppressions.

Femmephobia

Why are tomboys treated differently than sissies? Why are words like *pansy, sissy, ladies, fairy, diva,* or *princess* viewed as biting pejoratives, whether directed at women, men, or nonbinary folks? These terms would not be seen as an insult were femininity not seen as something subordinate—namely, subordinate to masculinity. There is an abundance of terms for different types of prejudice rooted in femininity, such as *transmisogyny, transmisogynoir, femi-negativity, sissyphobia, anti-effeminacy, slut-shaming, effemania,* and *misogynoir.* Each term is used to describe the targeting of specific social groups (e.g., trans women and trans women of color, gay men, Black women). Scholars have recently begun to examine how these different concepts commonly devalue and regulate femininity, which they term *femmephobia*. Thus, while sexism and misogyny refer to oppression based on gender (i.e., woman) or sex (i.e., female), femmephobia refers to oppression based on gender expression (i.e., femininity). It is important to understand the origins of femmephobia in order to comprehend its three key trajectories: femmephobia in reference to anti-femininity, femmephobia as a form of gender policing, and femmephobia as a theoretical framework.

Origins and Trajectories of Femmephobia

The term *femmephobia* originated as a means to characterize the disparaging of femme lesbians,

but it is increasingly being used to describe oppression both inside and outside of LGBTQIA+ communities. Similar to the way that *femme* has branched out from its origins in lesbian communities, femmephobia has come to represent the variety of ways that femininity is devalued, regulated, and policed. Thus, femmephobia refers not only to femme identities and the targeting of femme-identified individuals (i.e., a phobia of and discrimination against femme people) but also to the overarching devaluing of femininity (i.e., anti-femininity) and the gender policing of feminine norms. The concept of femmephobia also offers a framework through which gender-based oppression can be better understood.

Femmephobia as Anti-Femininity

As a social and systemic phenomenon, femmephobia refers to deep-seated anxiety over femininity and feminization, as well as the overarching fear and hatred of femininity, separate from people's gender and sex. Broadly conceived, femmephobia has been described as aversion to femininity and prejudice and discrimination against those who exhibit traits associated with femininity. Similarly, femmephobic attitudes are ones that devalue femininity and endorse masculinity, such as by privileging traditional masculine behavior and ways of thinking.

Femmephobia as Gender Policing

Femmephobia also functions as a type of gender policing that requires individuals to conform to a narrow range of feminine norms in order to be acceptable as female. In other words, femininity can only be ascribed to those who meet the "checklist" of feminine rules, which includes, but is not limited to, being assigned female at birth, heterosexual, white, thin, able-bodied, passive, compliant, and neither a Madonna nor a whore. For example, femmephobia prohibits trans men and nonbinary people from being able to access or express femininity. Trans women are also denied access to femininity, or their femininity is seen as inauthentic, but they are simultaneously required to perform femininity in order to be authenticated as women.

Femmephobia is a response to bodies and identities that do not adhere to these standards, with the goal of maintaining the established boundaries of patriarchal femininity, as well as femininity's subordinate status to masculinity. However, even "acceptable" femininity is still susceptible to femmephobic views because it is seen as inherently inferior. Therefore, both dissident and "normative" femininities can be subjected to femmephobia due to societal attitudes that devalue *and* regulate femininity.

Femmephobia as a Framework

Femmephobia not only regulates femininity that deviates from patriarchal norms but also protects and naturalizes masculine power. In this way, femmephobia is a lens through which society predominantly makes sense of femininity: how it signifies weakness and vulnerability, as well as is limited to individuals who are assigned female at birth and sexually available to men. Importantly, femmephobia brings together the multiple invocations of anti-femininity outlined above. Thus, what makes femmephobia "femmephobia" rather than, say, "transmisogyny" or "slut-shaming" is its recognition that anti-femininity is systemic and deeply ingrained. Inherent in its meaning, femmephobia is the recognition that the devaluation and regulation of femininity spans intersecting axes of identity. Rather than looking at these systems in isolation, femmephobia is a concept that connects and recognizes the multiple ways in which femininity is devalued and regulated, as well as brings these conversations together. As a result, discussions of femmephobia must be seen within the context of broader anti-feminine attitudes and systemic forms of oppression.

Femmephobia, Gender Hegemony, and the Gender Binary

Gender hegemony refers to the ways that masculinity is elevated over femininity, but this notion is typically used only in relation to power dynamics between men and women. Expanding on the concept of gender hegemony, femme theorists have argued that masculinity is privileged independently of "men." Their work suggests that the gender binary is not merely divided down the center, with "men" on one side and "women" on the other. Rather, it is divided horizontally, with masculinity

figuratively and socially on top and femininity on the bottom. By bringing together the different ways that femininity is devalued and regulated, such an analysis suggests that the gender binary is a hierarchical separation maintained through femmephobia.

Fertility Preservation

Gender-affirming interventions significantly improve the mental health, quality of life, and sexual health of trans individuals. Some gender-affirming medical and surgical treatments present risk of diminished fertility or infertility. Various assisted reproductive technologies (ARTs) allow for trans individuals who desire future biological children to preserve their reproductive capacity, depending on factors related to the age at which they first received medical intervention and the form of the intervention(s). Fertility preservation (FP) encompasses the cryopreservation, or freezing, of gametes (oocytes/eggs or spermatocytes/sperm), gonadal (ovarian or testicular) tissue, or embryos (a fertilized egg) prior to initiation of treatments that potentially or certainly impair fertility, with varying options based on sex designation at birth and stage of physiological development (e.g., pubertal; postpubertal). Uptake of FP depends on many competing psychosocial, structural, and interpersonal factors. This entry provides an overview of fertility-related effects of gender-affirming interventions, current and potential future FP options, barriers to utilization, experiences of FP among trans individuals, and suggestions for providing gender-affirming fertility-related care.

Effects of Gender-Affirming Treatments on Fertility

Gender affirmation is an individual experience and may include various social, medical, and surgical components that help trans individuals' gender identity align with their body and social experiences. Some, but not all, trans people seek gender-affirming medical and/or surgical treatments when they are available to them. Gender-affirming surgical interventions that involve removal of reproductive organs—such as hysterectomy and bilateral salpingo-oophorectomy (removal of the uterus, fallopian tubes, and ovaries) and orchiectomy (removal of the testicles)—cause permanent loss of fertility. The two main gender-affirming medical treatments include puberty blockers and hormone therapy. The extent of the impact on fertility largely depends on the individual's stage of physiological development, as well as type and duration of medical treatment, as discussed below.

Effects of Puberty Blockers on Fertility

For trans youth, the first step in gender affirmation may involve the use of puberty blockers, or gonadotropin-releasing hormone analogs (GnRHa), which delay and prevent the development of secondary sex characteristics. One benefit of puberty blockers is they are typically considered benign and reversible (although this has not been verified through research on potential medical/neurodevelopmental and/or social impacts). Puberty blockers are commonly used to treat children with precocious puberty, without known negative effects. However, with current reproductive technologies, trans youth who receive

gender-affirming medical treatments at Tanner 2 (soon after the onset of puberty) and progress directly to gender-affirming hormones (GAHs) may not have the opportunity to preserve fertility. Youth assigned male at birth whose puberty is blocked will not likely produce sperm. Youth assigned female at birth whose puberty is blocked will have immature oocyctes/eggs, unable to be fertilized. Thus, at a very young age, children, and their parents, are making decisions with implications far into the future; individuals who as children initiated puberty blockers and subsequent GAHs may first start to realistically understand their parenthood desires and goals in adulthood, many years from when gender- affirming medical interventions were started.

Effects of Estrogen Therapy on Fertility

For trans youth assigned male at birth, undergoing feminizing gender affirmation without having first received GnRHa inhibitors, estrogen therapy suppresses the hypothalamic-pituitary-gonadal axis, blocking the release of testosterone and facilitating the development of characteristically female attributes such as breasts. As a result of reduced testosterone, penile and testicular atrophy and impaired spermatogenesis may occur, meaning that the production of mature sperm is reduced. Extended estrogen therapy increases this atrophy and may permanently stop spermatogenesis during estrogen treatment. Discontinuing estrogen therapy among trans women has been associated with mixed results with regard to reversibility and an increase in sperm production, including the potential for pregnancy without the need for ARTs. Research is not yet conclusive, however, due to a number of factors, including (a) the relatively short time that gender-affirming medical treatments have been available as standard of care, (b) variability of hormone regimens, (c) age at which GAH therapy began, (d) age of GAH therapy discontinuation, and (e) small sample sizes of existing studies.

Effects of Testosterone Therapy on Fertility

For trans individuals assigned female at birth desiring masculinizing medical interventions and who have not taken puberty suppressers (and therefore have mature oocytes), the evidence regarding the long-term impact of testosterone therapy on fertility is mixed. The majority of trans individuals report amenorrhea (the absence of mensuration) while using testosterone therapy. There is also evidence of anovulation—where ovaries do not release an oocyte during menstruation—among a majority of trans individuals within several weeks of beginning testosterone therapy, likely due to suppression of the hypothalamic-pituitary-gonadal axis. Nevertheless, unintended pregnancies have been reported among trans men while on gender-affirming testosterone therapy. There is evidence that exposure to testosterone does not affect the ovarian reserve and that if one ceases taking testosterone, they will possibly be able to achieve fertility without requiring ARTs. As of yet, there are no data suggesting negative effects on children born from trans individuals after they have received GAH intervention, although, again, this is understudied.

Fertility Preservation Options

With the introduction of ARTs, there are a variety of family-building options, both established and experimental, for trans people seeking gender-affirming treatments who desire genetic children in the future. Fertility preservation encompasses the cryopreservation, or freezing, of gametes (reproductive cells), gonadal (reproductive organ) tissue, or embryos (a fertilized egg) before exposure to treatments that may impair fertility. ARTs afford trans people the option to preserve future reproductive options prior to the inception of gender-affirming medical and/or surgical interventions. Fertility preservation options vary based on sex assigned at birth and stage of puberty.

Fertility Preservation Options for Individuals Assigned Female Sex at Birth

For trans individuals assigned female sex at birth who are pubertal (i.e., have experienced menarche, or the first menstrual cycle), cryopreservation of oocytes (eggs) and embryos are established methods for FP. Both options require hormonal ovarian stimulation for oocyte retrieval and subsequent banking (storage) of oocytes or embryos for future conception using ARTs. Testosterone therapy will need to be discontinued prior to initiating

FP, although the ideal duration of discontinuation is currently unknown. Trans youth using puberty blockers may need to discontinue their use until experiencing menstruation for FP. Ovarian stimulation lasts for approximately 2 weeks to increase the development of several mature oocytes. During the stimulation period, the ovarian response is monitored with transvaginal or transabdominal ultrasound—transabdominal monitoring may be preferable. Embryo cryopreservation and banking involves fertilizing the patient's egg with sperm from a partner or donor for in vitro fertilization. For trans individuals assigned female sex at birth, retaining the uterus—but not necessarily ovaries—is required for those who desire the option for becoming pregnant in the future. Alternatively, a pregnancy can be carried by a partner or surrogate (gestational carrier).

For prepubertal trans individuals assigned female at birth, ovarian tissue cryopreservation became an established option for FP as of December 2019. Ovarian tissue cryopreservation involves obtaining part of or an entire ovary to be frozen and stored. Unlike oocyte or embryo cryopreservation, ovarian tissue cryopreservation does not require ovarian stimulation and is possible for individuals already receiving surgery to remove the ovaries during the surgery and freeze the tissues for later autologous transplantation (i.e., tissue returned to the patient's own body). The tissues are frozen and reimplanted when a pregnancy is desired. There is controversy over the use of frozen ovarian tissue among trans youth; presently, only autologous transplantation has been successful, as evidenced in cisgender (cis) women who did ovarian tissue cryopreservation prior to cancer treatment. Additional ARTs may be needed for a successful pregnancy, which could require estrogen and progesterone treatments. Such treatments and resulting side effects, such as breast growth and the return of other feminizing characteristics, may cause distress or exacerbate gender dysphoria for trans men and need to be weighed and considered along with the desire for genetic children.

Fertility Preservation Options for Individuals Assigned Male Sex at Birth

Fertility preservation options for postpubertal birth-assigned males include the established option of sperm cryopreservation and the experimental option of testicular tissue cryopreservation, which is available in some centers prior to puberty. However, as of 2020, testicular tissue cryopreservation has only resulted in a live birth from a primate. Testicular tissue cryopreservation has been conducted among cis males prior to cancer treatment; no patients have yet returned to use their frozen tissue, and thus no human births have occurred from this process.

Trans women have inquired about the possibility of uterine transplantation, a procedure currently being conducted in international clinical trials among women with a history of hysterectomy due to illness or medical conditions in which they were born without a uterus. The first known documented attempt of a uterus transplantation was in 1931 with Lili Elbe, a woman assigned male sex at birth who unfortunately died just 3 months after the procedure due to surgical complications. Since the first successful uterus transplantation resulting in a live birth in 2014, there have been over two dozen live births, some performed on women with congenital conditions such as Mayer-Rokitansky-Küster-Hauser syndrome. This procedure has not yet been attempted with trans women, and presently there are no trials to explore this option in that population. The uterine transplantation process is akin to other organ transplantation procedures such as liver and kidney, requiring the recipient to take antirejection medications while the uterus is in place and the suggested removal of the uterus after two live births. In the current trials, there have been reports of frequent serious life-threatening complications, and more cis women have failed to achieve pregnancy and live birth than those with a successful outcome.

Perceptions and Experiences of Fertility Preservation

Trans individuals' interest in FP and parenthood vary widely. Trans youth tend to report less interest in biologically related children than adults—although many trans youth indicate their feelings may change in the future. Despite interest, studies indicate that as few as 3% of trans adolescents and young adults undergoing gender-affirming medical and/or surgical treatment pursue FP, with the lowest rates among youth assigned female sex at birth.

A significant proportion of trans adults have expressed that they would have pursued FP options if it were an option when they sought treatment, and many trans adults and youth alike have indicated a need for better communication about potential infertility and FP with providers. Nonbinary individuals have rarely been reported on separately from binary individuals in terms of reproductive and fertility counseling needs. This is a critical priority for further clinical research, so clinicians can adequately meet the needs of all gender-diverse individuals.

Natural Conception

In the reported cases of planned pregnancy in trans adult men, they initially suspended the use of hormones to conceive and the pregnant person remained off hormones. In some cases of trans men experiencing pregnancy, the overall experience may cause emotional stress and disharmony, with some pregnant trans men feeling they have "stepped backward" in their quest for living their authentic life. These feelings likely vary by individual as well as actual desire for pregnancy and whether the pregnancy was intentional versus accidental. Trans men who have experienced pregnancy after transition have noted low provider knowledge and a desire for support services unique to pregnant trans men. Many fertility clinics do not have patient education materials or information relating to trans populations on their websites or in their offices, suggesting to potential patients that access to ARTs and other services may not be welcoming.

Adoption

Some trans youth express a desire to adopt a child and have no interest in biological children. While many adults consider adoption an excellent alternative or even the first desire to create a family, the process can be expensive, arduous, and sometimes fraught with disappointment. Trans people may experience additional obstacles in the adoption process not encountered by cisgender adults, such as implicit or explicit biases toward trans individuals. There are scant data on trans people's experiences with adoption as either a single-parent or two-parent household. Literature from same-sex and single-parent adoptions suggests children raised in such homes are equally loved and well adjusted, if not more so, than in coupled cisgender parent households, although this research is limited with regard to families with one or two trans parents.

Barriers to Fertility Preservation

Structural Barriers

FP costs may be prohibitive in countries such as the United States, where financial assistance is limited depending on health insurance and state of residence. Trans individuals seeking FP in other countries may have no financial barriers because procedures are covered by national health insurance. However, even in countries where FP is covered, such coverage may not be extended to trans youth and may be available only for cisgender people undergoing other treatments that affect fertility, such as chemotherapy. Additionally, not all ARTs are available in every country. For example, embryo cryopreservation may be restricted to married, cis couples. Experimental procedures such as testicular tissue cryopreservation are not available in every state in the United States and in many other countries.

Individual-Level Barriers

When counseling about fertility with trans youth, their developmental stage may be a barrier to pursuing FP or even discussing FP options. Trans youth, like cisgender youth, may not be developmentally able to predict their future reproductive desires—particularly during preadolescence. Some trans youth may be exclusively focused on their transition and desire to have their physical body align with their self-perception. In addition, psychosocial status, including low self-esteem, depression, suicidality, loneliness, and social isolation, may affect an adolescent's appraisal of life expectations, goals, and ability to be an adequate parent in the future. Whether this will result in future regret for not pursing FP remains unknown. Decisions about FP may be entangled with the specific body dysphoria a trans youth may be experiencing. If a trans girl or woman does not identify with the capacity for her body to produce sperm, the thought of masturbating to produce sperm to create future children may be abhorrent. A trans boy or man who does not identify with his

body's ability to become pregnant and give birth may eschew considerations of FP. The process of FP may be more onerous for individuals assigned female at birth versus those assigned male, with prolonged, invasive interventions difficult to contemplate or consider enduring for trans men. As mentioned above, another consideration is that children receiving puberty blockers may not be able to imagine themselves as parents or predict their adult desires. Some trans adolescents may have never had a romantic relationship and may be unable to imagine themselves in one in which they would want to coparent in the future. Some may be coming from families of instability and conflict, unable to imagine loving homes in which children are raised. All these factors and others can pose cognitive and emotional barriers to considering FP.

Another consideration is that youth may be unduly affected by parental desires to be grandparents and be persuaded to undergo FP procedures to support their parents or, in some scenarios, because they feel their parents will withdraw emotional or financial support if they do not follow their wishes. Other times, youth may want to preserve fertility but do not express this desire in order to spare parents the financial burden of such procedures. These are just a few of the ways in which an experienced mental health clinician can provide trans youth and family members with counseling to sort out these complex considerations. It is also imperative that medical clinicians carefully explain and review both the impacts of various gender-affirming medical interventions and the options for FP. Sometimes it can be helpful to present such information in multiple modalities (written and verbal formats) and/or in multiple sessions so youth and family are given adequate time to comprehend the information and explore their choices. Trans youth should be offered a discussion of FP with a variety of scenarios as to how stored gametes can be used and the idea that with rapidly changing technologies, there may be additional options in the future.

Interpersonal Barriers

Health care providers report many variables affecting their ability to provide adequate fertility counseling for trans youth, including (a) inadequate knowledge or training, (b) time limitations in busy clinics, (c) trans youth resistance to counseling, (d) developmental considerations (e.g., it can be difficult to talk to young children meaningfully about FP), (e) complex family dynamics, and more. Systematic training and curricula for medical and mental health providers are lacking in this area, as is research regarding best approaches and possible regret for trans adults who refrained from FP as youth. Because this is an understudied area, research from other areas can be useful to provide guidance on counseling best practices. General guidelines on pediatric fertility counseling have been published, applicable across pediatric conditions, and subspecialty areas such as oncology have also published some guidance that can be useful, although the specific concerns in trans youth and families are unique. Extrapolating from general best practices, in combination with knowledge of trans youth needs, some guidelines for fertility counseling with transgender youth have been published. These recommendations include ensuring that providers have adequate knowledge, developing a standard protocol for counseling, optimally including both mental health and medical providers, and, drawing from general pediatric literature, employing a shared decision-making approach (i.e., clarifying which decisions and choices are available, reviewing knowledge of parenting options, discussing personal values, discussing each parent and child's perspective openly, etc.). Ideally, this would be an interdisciplinary, multisession process. However, providers may walk a fine line when discussing FP with trans youth, especially in situations in which youth are highly distressed and anxious for GAHs, when they express resistance to such discussion and certainty that they do not want to engage in FP, or when it is clear they do not have the financial resources to cover FP costs. Curricula for providers and research on best approaches to the decision-making process should help ensure the provision of optimal counseling in this complex and evolving area and ultimately facilitate satisfaction with FP choices.

Fiction

Trans fiction is a rapidly developing field of literature consisting of novels and short stories focused on trans subjects. Trans fiction offers representations of gender diversity, encourages greater understanding of trans experiences, and imagines new ways of existing in the world. In contrast to many other forms of trans narratives (e.g., legal case studies, medical reports, news articles), fiction is not tethered to the world as it is; instead, it can describe what might be. Thus, this type of storytelling opens up new possibilities for trans subjects and potentially fosters greater empathy from a reading audience. This entry examines key issues and trends in trans fiction and includes examples of influential works in the genre.

Definition

Defining the term *fiction* is relatively straightforward: Fiction refers to imaginative narratives such as novels or short stories. Fiction creatively constructs characters and events, and it invites the reader to envision experiences from another's perspective. Defining *trans fiction* is a bit trickier. Just as the umbrella term *transgender* may mean different things to different people, the category of "trans fiction" also has contested meanings. The most inclusive definition describes all creative

prose narratives produced about, by, or for trans people. Some argue, though, that trans fiction should refer primarily to works written by trans authors or for trans readers, so that these actual individuals are prioritized and supported. Strengthening this position is the fact that many non-trans authors have misrepresented or exploited trans identities in their creative works. While acknowledging this issue, this entry ascribes to the more expansive definition and includes all fiction centering trans subjects—that is, works written by trans authors, as well as those featuring trans themes and/or characters—in order to provide a comprehensive overview of the category. As is the case regarding any sort of literary classification, there are often rigorous debates over which works should be included or excluded; these discussions can serve as ongoing, productive opportunities to reevaluate priorities and reexamine representations over time.

History of the Genre

From *The Arabian Nights* to *Torikaebaya Monogatari,* and from Greek myths to Ovid's *Metamorphoses,* gender identities have been explored and depicted in stories for generations. Since the latter half of the 20th century, though, there has been a marked rise in influential trans literature. The narratives found specifically in fiction offer a unique window into trans characters and relationships. Unlike other forms of representation, the genre of fiction encourages the reader to imagine the world from another's point of view; furthermore, the reader spends significant time with the characters, building empathy and evaluating multiple subject positions (e.g., those of the characters, the narrator, the writer). Works of trans fiction often contain contradictions, ambiguities, and questions left out of more factual accounts, and they offer imaginative explorations of what trans experience has been, is, and could potentially be.

When considering the history of trans fiction, there are two key levels of relevant literature: stories written in earlier eras that could be interpreted as trans works and stories written more recently (i.e., post-1960s) that are more overtly about trans experiences. While texts in the latter half of the 20th century often describe gender identities, experiences, and transitions using language developed in gender theory, earlier works describe trans experiences without such nomenclature. For example, Virginia Woolf's *Orlando* (1928)—which tells the fantastical life story of a character who survives centuries of British history, living first as a boy and later as a woman—is frequently cited and studied as a highly influential trans novel. In addition, *Nightwood* (1937) by Djuna Barnes and *The Well of Loneliness* (1928) by Radclyffe Hall—stories traditionally read as depictions of same-sex dynamics and desires—also have strong trans elements.

In the latter half of the 20th century, critics and writers began to tease out distinctions among gender, sexuality, and sex, leading to works that engaged with trans themes more explicitly. Gore Vidal's campy, sexuality-focused novel *Myra Breckinridge* (1968), for instance, aggressively subverts traditional sex and gender rules. John Rechy's *City of Night* (1963) is similarly explicit, but while *Myra Breckinridge* is satirical, *City of Night* paints a starker, truer-to-life picture (e.g., Rechy refers to the 1959 Los Angeles Cooper Do-nuts Riot). Novels like these innovatively pushed boundaries of how gender performance and sexual acts could be represented in fictional works.

The general field of trans literature in these decades was dominated largely by critical and creative nonfiction, though, and not by creative fiction; it is not until the end of the 20th century that trans fiction truly comes into its own. Many point to the 1993 publication of trans writer Leslie Feinberg's *Stone Butch Blues* as a key moment for this literary genre. This work, frequently lauded as the most influential trans novel, recounts important moments in the 20th-century LGBTQ+ movement as experienced by Jess Goldberg, a protagonist who explores gender and sexuality as a butch lesbian, a trans man, and a gender-nonconforming individual.

Since trans memoirs were such an influential form of literature in the 20th century, many trans novels follow their style. While there are certainly other narrative structures within literary trans fiction, this trend is common enough to warrant attention. Novels written in this fashion are generally inspired by real events that occurred to the author—such as *Stone Butch Blues*—and/or structured along the lines of a memoir, with a first-person protagonist recounting their life story—such as Kai Cheng Thom's fantastical coming-of-age tale

Fierce Femmes and Notorious Liars: A Dangerous Trans Girl's Confabulous Memoir (2016).

Since the 1990s, trans fiction has rapidly developed from a tenuous genre (e.g., in 2010, Lambda Literary published an article asking, "Is There, or Should There Be, Such a Thing as 'Trans Lit'?") to an established one (e.g., in 2020, most U.S. library systems include "trans fiction" as a searchable category). Trans fiction influences popular culture not only in its original form but also in how these stories evolve and proliferate. For example, the award-winning literary fiction novel *The Danish Girl* (2000), by David Ebershoff, was adapted into an Academy Award–winning film. Moreover, access to trans fiction continues to increase, as advocates push for greater inclusion of trans works in schools and libraries, as well as for greater support of trans voices by major publishing houses.

Publication Considerations

Historically, fiction by trans authors has often been marginalized and perceived as intended for a niche market, and thus such authors have relied on small, independent presses to get their work to readers. For example, Topside Press focuses explicitly on trans literary fiction, such as Imogen Binnie's *Nevada* (2013) and Sybil Lamb's *I've Got a Time Bomb* (2014). In *Nevada*—a novel that Binnie states she wrote for other trans women—she describes a punk trans woman's road trip and efforts to figure out love, work, and identity. *I've Got a Time Bomb* is an edgy, punk, countercultural novel that depicts a frequently marginalized trans protagonist who experiences similar violence and challenges as Lamb has herself. While these two novels are well known within the trans community, they have not received significant attention from the general public.

In contrast, works by well-established cis authors on trans themes have garnered attention from more mainstream publishers—a frustrating situation for many trans readers, writers, and activists eager to hear stories from their own community. For instance, one of the more widely read such novels is Jeffrey Eugenides's best-selling, Pulitzer Prize–winning *Middlesex* (2002), which was published by Farrar, Straus, and Giroux. In this epic story of the Greek American Stephanides family, the intersex protagonist decides to transition from identifying as the feminine Callie to the masculine Cal. Best-selling novelist Chris Bohjalian's *Trans-Sister Radio* (2000)—which was published by Vintage—likewise focuses on the (somewhat unrealistic) gender transition process of Dana Stevens, who is in a passionate relationship with a single mother, Allison Banks. The success of trans-focused works by already established cis authors like Eugenides and Bohjalian has proven that a market for such stories exists, which, in turn, creates space for more narratives exploring trans subjects. In 2018, for example, trans author Jordy Rosenberg's debut novel *Confessions of the Fox* was published by Random House and received multiple awards and accolades (e.g., *The New Yorker* book of the year, Lambda Literary Award finalist). Ideally, trans writers will continue to move from the margins to the center to tell their own diverse and creative stories.

Beyond Literary Fiction

While the preceding examples of literary fiction are important and influential texts, other types of novels also speak to trans subjects. Trans fiction narratives continue to diversify in both style and form, but as of 2020, key subgenres include the following.

Young Adult Fiction

Young adult (YA) fiction can provide both relief from the stress of adolescent life as well as models for how to navigate shifting identities and new experiences. Representation is especially important in YA texts because teenaged readers often struggle to understand their changing bodies, desires, and sense of self. By demonstrating multiple ways of being, this genre creates avenues for validation, empathy, and community, which is why trans YA fiction is so significant; trans stories are not limited to adult experiences. Considered by many to be the inaugural YA trans novel, Julie Anne Peters's novel *Luna* (2004) is told from the perspective of an adolescent girl whose older sibling is trans. Another notable work is Ellen Wittlinger's *Parrotfish* (2007), which describes high schooler Grady's quest to both blend in and express himself. Many YA works focus on romance, and trans YA fiction is no exception. For instance, Meredith Russo's *If I Was Your Girl* (2016) tells an engaging story of adolescent love as experienced by its narrator Amanda, whose recent gender transition complicates her romantic

life. Crucially, trans YA fiction can provide young trans readers with assurances that they are not alone, as well as show examples of how to navigate the changing—and often challenging—world of gender expression.

Children's Fiction

For younger readers, there is a new and growing field of children's fiction centered on trans themes. Children's illustrated stories range from those that explicitly reference gender performance—for example, Kyle Lukoff's *When Aidan Became a Brother* (2019) and Erica Silverman's *Jack (Not Jackie)* (2018)—to those that approach the topic in a more symbolic manner—for example, Michael Hall's *Red: A Crayon's Story* (2015) and Airlie Anderson's *Neither* (2018). These stories offer parents an opportunity to discuss gender diversity and expression on a simple, child-friendly level. Trans characters are increasingly represented in stories for later elementary and middle school readers as well. For example, Cat Clarke's *The Pants Project* (2017) depicts an 11-year-old protagonist, Liv, who feels frustrated by a middle school dress code that does not give him the option to wear pants; since everyone still sees him as Olivia, he must wear skirts to school. Liv's efforts to change his school's policies run parallel to larger struggles for diversity and acceptance, while the tone and plot keep this story on a young reader level. Trans-focused novels for middle school students can both reflect common preteen experiences, such as feeling socially isolated or misunderstood, as well as expand such readers' understanding of identity development. Ami Polonsky's *Gracefully Grayson* (2014), for instance, is a middle-grade novel about a preteen, Grayson, who is seen by family and peers as a boy but who actually longs to express herself as a girl. Another novel with similar themes—even including the pivotal plot point of playing a girl's part in a school play—is *George* (2015) by Alex Gino, a self-identified genderqueer writer. In this story, fourth-grade student George secretly wants to identify as Melissa, and the narrative traces her process of sharing this sense of self with family and friends.

Speculative Fiction

Fantasy, science fiction, and speculative fiction offer glimpses of other ways of being, from magical adventures to distant worlds to dramatic scientific advances. These forms of storytelling have long provided spaces to work out social questions regarding gender and identity. For example, *The Left Hand of Darkness* (1969), by Ursula LeGuin, imagines an ambisexual population on the planet Gethen. More recently, the *Transcendent* series, which began in 2016, annually anthologizes short stories focused on trans experiences in the genres of speculative fiction, fantasy, science fiction, and horror. In contrast to realistic fiction, these genres are not bound by actual circumstances, logistics, or facts. As they open up new worlds to readers, such novels also often reflect on issues in our own world, as Jeanette Winterson's *Frankissstein* (2019) does when it blends speculative and historical fiction approaches to tell the stories of trans doctor Ry Shelley in the early 21st century and author Mary Shelley in the 19th century.

Historical Fiction

Historical fiction blends imagination with research to create new insights into our past and present. Within this genre, novels set in earlier time periods may depict trans characters without explicitly referring to them as such in order to maintain historical accuracy, as Patricia Powell does in *The Pagoda* (1998), which describes Jamaica in the late 1800s through the eyes of Lowe, a nonbinary Chinese immigrant. By setting trans stories in previous eras, historical fiction demonstrates the long, ongoing relationship individuals have had with gender. Moreover, novels that include famous historical figures can reconfigure our understandings of former times. In addition to Winterson's *Frankissstein,* another leading work of historical fiction is Rosenberg's *Confessions of the Fox,* which reimagines Jack Sheppard, the famous 18th-century British criminal, as a trans man.

Romance Fiction

Within the genre of romance novels, both writers and publishers have responded to readers' calls for greater diversity in the kinds of characters and relationships featured. Trans romance novels are part of this gradually expanding and increasingly inclusive field, such as *Roller Girl* (2016) by Vanessa North, whose writing has been recognized

by both the Lambda Literary Foundation and the Romance Writers of America. Beyond the specific genre of romance novels, romantic storylines frequently appear in YA literature, as noted above, as well as in literary fiction with more adult themes (e.g., in Binnie's *Nevada*).

Short Fiction

In addition to the many novels in this field, short fiction works abound as well, as found in the 2012 anthology *The Collection: Short Fiction From the Transgender Vanguard,* which features diverse works from 28 trans-identified authors. One of the more notable single-author collections is *A Safe Girl to Love* (2014) by trans writer Casey Plett; each of its 11 short stories relates the adventures in love, loss, and young adulthood experienced by trans women characters. Plett also coedited with Cat Fitzpatrick the short story anthology *Meanwhile, Elsewhere: Science Fiction and Fantasy From Transgender Writers* (2017). This collection offers innovative, clever representations of trans life, and the focus is consistently on complex character development rather than simple character stereotypes. Short story collections have the advantage of providing multiple perspectives on trans experiences side by side, which can clearly demonstrate the diversity and complexity of this subject.

Controversies and Challenges

The Role of the Author

In contrast to creative nonfiction accounts such as memoirs, in fiction, the author and the protagonist are not the same person, which leads to questions about who has the right to tell what kinds of stories. In trans fiction, there are works focusing on trans characters written by trans authors, as well as works by cis authors. Some argue that cis authors should not write about trans characters since they lack direct, personal experience. For example, after the publication of his novel *My Brother's Name Is Jessica* (2019), John Boyne received considerable backlash from trans activists. Boyne defended the work, saying that although he is not trans, the point of the genre is to imagine others' experiences—otherwise, authors would be limited to writing only autobiographies. When cis writers depict trans characters in their fiction, though, trans people are understandably anxious that such representations may flatten, demean, or exploit their real-life experiences. Historically, depictions of trans characters have often appeared as comedic, deceptive, or tragic figures that many readers refute as inaccurate and/or two-dimensional portrayals. Furthermore, some trans people argue that since cis writers dominate the publishing industry, greater efforts should be made to correct this underrepresentation by including the voices of trans writers telling trans stories. The other side of this discussion focuses on the fact that the heart of fiction is imagination; authors should not be confined to describing only events and experiences they have personally gone through. Moreover, to insist that only trans writers should write trans stories potentially places an unfair and disproportionate burden on these writers, since they would then be the only ones addressing gender identity topics in their work. In addition, while some trans authors do indeed choose to focus on trans characters, they should not be pigeonholed into writing only such narratives.

With so relatively few trans stories garnering attention, there is understandable criticism when cis writers seem to appropriate trans experiences in their narratives. And yet, at the core of fiction writing is the act of conceiving other ways of being and transporting readers into these imaginative worlds. Balancing a desire for authenticity with an openness to creative interpretations appears to be an ongoing challenge for trans fiction as a field.

Formulaic Fiction

Indicative of the challenges regarding the relationship between the author and the text, a specific criticism levied at some trans narratives—typically those written by non-trans authors—is the repetition of the formulaic "wrong body" narrative that focuses too narrowly on transition. In this construction, the trans character suffers because they feel that they have been born into the wrong body, and they must make their body align with their inner sense of self to find happiness. The problems with this plot are that it often oversimplifies the multifaceted trans experience, locates the discussion of gender difference in purely physical and/or medical terms, fails to question rigid gender norms, and, because it is so commonly told, implies that

there is a singular, dominant trans experience. Moreover, by concentrating so heavily on the transition experience, such a plot misses other varied and intriguing elements of a trans character's existence, and it all too often emphasizes loneliness, trauma, and tragedy. For example, the protagonist of cis writer Kim Fu's *For Today I Am a Boy* (2014) undergoes one painful experience after another related to sex and gender. In contrast, Plett's novel *Little Fish* (2018)—which was written expressly for a trans audience—depicts a trans woman's unraveling of a family mystery and offers a complex, nuanced tale of human experience. Trans fiction has developed a great deal in only a few decades, and there is good reason to be optimistic that many more diverse and insightful works will be written in the years ahead.

Film

Film has played an important role in the public perception of trans people. It is important to understand this role because popular media are among the primary ways that people encounter members of marginalized groups. Trans people and other members of the LGBTQIA+ community also often use popular media texts as sources of role models to help them understand their own experiences. In order to contextualize the role played by film, this entry first considers how representation can help shape perceptions of marginalized groups. It then discusses the history of trans representation in film and the different genres that are prominent in trans films. The entry concludes with a discussion of how the increased presence of trans people in the film industry can help address the concerns identified with trans representation in film. While trans people are increasingly involved in the production of film and other media, the representations found in film have an impact on trans lives with or without that involvement.

Representation in Film

Representation in film matters because it serves as a symbolic stand-in for the group being portrayed, creating the potential for deeper knowledge and understanding of the experiences of members of the group than would be possible through direct social interaction. At issue with film representations of trans people and other marginalized groups is that the groups have historically been represented only from a very narrow perspective on their lives. Dominant groups, such as white people and cis men, receive a wide variety of representations across hundreds of films released each year, so any one depiction of the group does not have much of an impact. When representation is more limited, as it is for trans people and other marginalized groups, each depiction has a far greater impact on the public's understanding of the group. It is important to be aware of these limitations in representation when discussing the depictions of any marginalized group in film.

Representation in film has these limitations when it comes to the depiction of marginalized groups because of its ability to constitute and

constrain. According to media theorist Stuart Hall (2013) in *Representation: Cultural Representations and Signifying Practices,* representation is constitutive of events in the sense that our understanding of them is shaped by how they are framed for or by us, not solely through our unfiltered experience of them. Let us say you are walking down the street, and you see someone walk away from their car without putting any money into the parking meter. You think to yourself, "Hey, that's wrong! You have to pay when you park here," but your understanding of the event can only be understood as wrong because of how you have framed it based on your morals and legal knowledge. Even though you are experiencing the event in the moment, it functions as a representation because you had to filter it through your own perspective in order to make sense of it. Likewise, in terms of film representation, how a group is generally depicted comes to constitute how they are perceived. This is especially important for marginalized groups because of the limited amount of representation they receive. If a marginalized group is repeatedly depicted in negative ways, as with Muslims being depicted as terrorists or Black people being depicted as violent criminals, the representation comes to constitute how the group is understood in society in general. The constitutive nature of representation makes us aware of how depictions in film and other media have potential impacts outside of the medium itself.

According to film scholar Stephen Heath in *Questions of Cinema,* representation is also constraining because it seeks to provide order to events by limiting the information available to us. No event can be presented in its entirety, so any representation is the result of decisions about what to present and what to leave out. Returning to the parking meter example from before, as you grumble to yourself about how no one follows the rules anymore, you may miss the person in question running into a nearby Starbucks to get change from their partner or pulling out their phone to pay with an app. Your understanding of the event may be extremely limited by how you represent it in your mind. When we expand this even further by considering the scope of film representation, the constraining effect becomes even larger. The depiction of marginalized groups in film tends to follow established patterns, so the groups are portrayed in very limited ways. When film representation serves as a primary way in which audience members encounter marginalized groups, their views come to align with the limited depictions seen on screen. The ability of representation to constitute and constrain must be taken into account in any discussion of trans representation in film.

Trans Film History

Trans representation in film has existed since the beginning of the medium. While the crossdressing characters typically featured in these films and throughout the history of trans representation would not self-identify as trans, these films still have an impact on public perceptions of trans people, so they must be considered. In *Hollywood Androgyny,* media scholar Rebecca Bell-Metereau examines changing attitudes toward women and men in society through tracing the early history of trans representation in film, from pioneering comedies like Buster Keaton's *Our Hospitality* (1923) and Charlie Chaplin's *The Masquerader* (1914) and *A Woman* (1914), to historical dramas and Westerns featuring masculine women like *Queen Christina* (1933) and *Johnny Guitar* (1954), to films like *Psycho* (1960) that challenge the audience's status quo, to finally ending with a consideration of early efforts to humanize trans characters in films like *Little Big Man* (1970). Films before the 1960s operated under the Hays Code, a set of self-regulatory guidelines created by the film industry that placed severe limitations on film content. In terms of the representations of trans women during this period, films like *All-American Co-Ed* (1941) and *Charley's Aunt* (1941) used crossdressing by cis men as a device for wacky hijinks and to facilitate heterosexual romance. By the end of the films, the gender binary was firmly in place, and the characters' crossdressing was seen as nothing but a momentary aberration. Representations of trans women in this period generally reduced their identities to nothing but a temporary disguise.

It is not just trans women who faced limiting representations in early film. Representations of trans men built on a tradition of masculine women in film but sought to reinforce their innate femaleness, rather than allow for challenges to the gender binary or recognition of trans identities. Historical films and westerns kept masculine women

confined to the past. Tomboys were allowed to accompany male leads in films like *Sullivan's Travels* (1942), but their transgressive potential was reduced by limiting them to sidekick roles and having them embrace their femininity after falling in love with the male lead. Efforts were made to challenge these limiting depictions during this period, most notably Marlene Dietrich's sensuality in her role as a masculine woman in films like *Morocco* (1930), but the representations of trans men were still generally focused on reinforcing the gender binary. Early film history for trans men, as for trans women, would mostly see trans identity treated as a costume worn by cis characters to play with the confines of a restrictive binary gender system without considering the realities of trans people's lived experiences. While these trends would persist in subsequent decades, the scope of trans representation in film expanded in important ways.

Films like *Some Like It Hot* (1959) and *Psycho* would begin to challenge the status quo of trans representation in film at the end of the Hays Code period. *Some Like It Hot* created space for transgression with its ending stating that gender identity was not important in matters of the heart, and in *Psycho,* Norman Bates's psychopathic killing spree is directly connected to his trans identity, a trend that would continue in films like *Dressed to Kill* (1980) and *Sleepaway Camp* (1983). These films forced the audience to consider trans identity in ways that did not reinforce a clear gender binary. With the Hays Code's ending in 1968 and its replacement by the modern ratings system, the challenges to the existing gender binary would continue to expand through underground films that rejected Hollywood conventions, such as John Waters's *Pink Flamingos* (1971), and the fusion of violence and camp in films like *Myra Breckenridge* (1970) and *The Rocky Horror Picture Show* (1975). This pairing of camp and violence as a means of resisting stereotypes would continue in films like *Ticked-Off Trannies With Knives* (2010). Beyond just resisting stereotypes, trans representation in film also began to try to humanize trans characters, such as in *Boys Don't Cry* (1999) and *Transamerica* (2005). Despite all of the efforts to expand and humanize the audience's conceptions of trans characters during this period, trans lives still remained a source of comedy. Films like *Tootsie* (1982), *Just One of the Guys* (1985), *Mrs. Doubtfire* (1993), *Big Momma's House* (2000), and *She's the Man* (2006) continued to focus on cis characters adopting trans identities as temporary costumes to address external problems.

The history of trans representation in film is marked by continued struggles between challenging gender norms and reinforcing traditional views. While efforts have been made in recent decades to humanize the depiction of trans people, trans representation in film still marginalizes trans people as objects of ridicule and fear. A historical approach helps reveal the trends in trans representation, but in order to get a fuller picture of the messages sent through these films, it is also important to discuss the genres into which these films are most frequently classified.

Trans Film Genres

The term *film genres* refers to the grouping of films around shared narrative and visual conventions or tropes, but according to Rick Altman in *Film/Genre,* it is the grouping of films that forms a genre, not the presence or absence of the shared elements in a particular film. A genre, such as the suspense thriller or action movie, is useful as a subject of analysis because it highlights similarities between different films that might not be obvious when viewing the films in isolation. Genre analysis gains its analytical power through this cross-film comparison, and it is important to remain focused on this comparison rather than on determining the classification of a single film based on the presence or absence of particular elements. It is also important to recognize that while a film may typically be identified as part of a certain genre, elements of other genres may be used in the depiction of particular characters. For example, *Ace Ventura: Pet Detective* (1994) is rightfully classified as a fairly broad, screwball comedy, but the depiction of the trans character in the film, Lt. Lois Einhorn, follows tropes more associated with thrillers in order to present her as a deceitful villain. If the film were analyzed solely as a comedy, the meaning of the depiction of Einhorn would be completely misunderstood.

Film genres are useful to audiences as a means to make connections between the numerous films they see over their lifetimes and to organize their viewing experience. Genres are useful to scholars as a means to make analytical connections between

films and to add further depth to understanding the meanings of these films. Although genre is a useful tool for audiences and scholars, the example of *Ace Ventura* serves as a reminder of the limits of genre and any form of classification and analysis. When discussing the dominant genres in trans film, the purpose is to understand how the films in the genre construct trans lives in specific ways and the possible meanings that can be made from those constructions.

As discussed earlier, comedy is one of the most prominent genres of trans film. Trans comedies generally focus on cis characters who are forced to adopt a trans identity in response to an external situation, for example, escaping from mobsters or trying to get a job as an actor after multiple rejections. The humor in these films often comes from the disjuncture that exists between the audience's perception of the main character as clearly cross-dressing and the perception by the other characters that the main character is the gender they claim. The audience laughs as Julie's father tries to flirt with Dorothy Michaels in *Tootsie* or at King Marchand's discomfort at having to pretend to be in a same-sex couple in order to date Victoria in public in *Victor/Victoria* (1982). Other humor comes from the characters' failure to adjust to their new gender roles, such as Daniel cursing the creator of high heels in *Mrs. Doubtfire,* Michael adjusting his stockings in public in *Tootsie,* and Adam constantly being called ugly while walking to class in *Sorority Boys* (2002). The message of trans comedies is that trans identity is temporary, it is something that is only adopted in response to an external stimulus, and trans people can never fully embody their gender identity. By making trans people and their lives the object of humor, trans comedies tell the audience not to take trans people seriously.

Horror films and thrillers are trans film genres that are united through the main message sent to the audience that they should stay away from trans people because they are dangerous. Horror films like *Psycho, Dressed to Kill,* and *Sleepaway Camp* depict trans characters as violent killers equivalent to other horror monsters like Jason from the *Friday the 13th* films or Freddie from the *Nightmare on Elm Street* films. While the characters in the horror and thriller films are more likely to identify as trans than the cis characters seen in trans comedies, their trans identities are often still the result of external forces, such as Norman Bates's physical isolation in *Psycho* or Angela having her trans identity forced on her by her aunt after the death of her father and sister in *Sleepaway Camp.* Their trans identities become the equivalent of monster disguises. The monstrous aspects of the characters are enhanced by the audience's never clearly seeing them when they attack their victims, as with Bobbie's black trench coat and sunglasses in *Dressed to Kill.* Their victims are usually cis characters trying to force them in some way to conform to gender norms, and their attacks send the clear message to the audience to stay away. The audience receives the same message in thrillers like *The Crying Game* (1992) and *Peacock* (2010). Instead of being depicted as violent monsters, the trans characters are portrayed as deceivers for not revealing their trans identities to others. The cis characters in the films are often caught up in dangerous situations as a result of their association with the trans characters and are generally disgusted upon discovering the trans identities of the characters, as when Fergus pukes in the sink upon seeing Dil naked for the first time in *The Crying Game.* The audience is told through these films that trans people are treacherous and should be avoided. This message can create dangerous situations for trans people when they engage in public life.

Unlike the previously mentioned genres, dramas like *Boys Don't Cry, Transamerica, Different for Girls* (1996), *Ma Vie en Rose* (1997), and *The Danish Girl* (2015) try to present trans people's lives in more sympathetic ways. Trans dramas give more attention to the experience of living as a trans person than other genres, such as showing Bree's process of getting ready in the morning at the beginning of *Transamerica* or Brandon's efforts to fit in with the other guys in his friend group by taking risks, like trying to hold onto a rope while being pulled by a truck or fleeing from the cops instead of pulling over in *Boys Don't Cry.* The films also attempt to show the trans characters receiving positive feedback, such as Calvin flirting with Bree in *Transamerica* or Paul's interest in seeing Kim naked, leading to them having sex in *Different for Girls.*

While these positive elements of trans representation are found in trans dramas, the films still end up focusing on the negative experiences of the

trans characters, such as Ludovic's emotional and physical abuse from her parents in *Ma Vie en Rose* and Brandon's rape and murder in *Boys Don't Cry.* The message to the audience in these films is that trans people may be deserving of sympathy because of everything they have had to endure, but their lives still exist outside of the norm and can never be fully understood by the audience. It is also important to consider the implication in these films that everything would be okay if the trans characters would just conform to gender norms.

These are just a few of the genres found in trans film. Others include the road trip film, where trans characters help a closed-minded community learn to be more tolerant, as in *To Wong Foo, Thanks for Everything! Julie Newmar* (1995), *The Adventures of Priscilla, Queen of the Desert* (1994), and *Hedwig and the Angry Inch* (2001), and films where crossdressed actors portray cis women or men, as in *Orlando* (1992), *Hairspray* (1988, 2007), and Tyler Perry's *Madea* films (2005–2019). There are also other traditions of trans representation that should be considered, such as the history of Black men crossdressing in film, as in *Big Momma's House, Juwanna Man* (2002), and *White Chicks* (2004); international films featuring trans characters, as in *Close-Knit* (2017) from Japan, *All About My Mother* (1999) from Spain, and *Sangharsh* (1999) and *Rafoo Chakkar* (1975) from India; and documentaries, such as *Paris Is Burning* (1990) and *Southern Comfort* (2001).

A review of different genres of trans film indicates that the dominant depictions are mostly negative and seem to show no interest in understanding trans people, which reflects that the primary audience for these films is cis people, not trans people. The implicit message is that cis people are uninterested in understanding trans lives, so their entertainment is prioritized over positive representation. Any efforts to improve trans representation need to show that cis people do care about understanding trans people or that trans people are a large enough audience to warrant making films directed at them.

The Future of Trans Representation

Although the constraints on positive representation of trans people are still in place, there is hope for change in the film industry. Most depictions of trans people across film history have been portrayed by cis people, but in recent years, cis actors like Jared Leto, Michelle Rodriguez, and Matt Bomer have been criticized for their portrayal of trans characters. More trans voices have also been included in the industry, both on screen, including trans actors like Laverne Cox, Jamie Clayton, Mya Taylor, Kitana Kiki Rodriguez, and Daniela Vega, and behind the camera, including trans directors and producers like Yance Ford, Sydney Freeland, Rhys Ernst, and Rosie Haber. Finally, trans indies like *Tangerine* (2015) and *A Fantastic Woman* (2017) have presented more nuanced and grounded portrayals of trans lives.

FRIENDSHIPS

This entry considers trans friendships. It examines friendships for trans men, trans women, and

nonbinary people; explores the benefits and barriers for trans people within friendship; and discusses how experiences differ across race and ethnicity, gender identity, and sexual orientation. The entry continues with an exploration of microaggressions and microaffirmations in trans friendships and concludes with a recommendation of directions for further research in the area of trans friendships.

Basic Definitions

Friendships are defined as meaningful, supportive nonromantic relationships with others who share affection and are mutually beneficial. Friendships often involve close relationships between two or more people, provide a source for giving and receiving support and validation, and are built around shared experiences or interests. Friendships are important for all people and are particularly important for trans individuals. Support and validation may or may not be present within families of origin for trans people, so friendships offer an opportunity to connect with others who are more supportive, have shared identities and overlapping interests, meet unique needs, and connect with others who understand trans experiences.

Patterns of Trans Friendships

Much of the extant scholarship on trans friendships focuses on patterns of friendships across gender identity and sexual orientation, as well as provides descriptive data about types of friendships. Research on trans friendships mostly lumps trans women, trans men, and nonbinary people into one homogeneous group and focuses on white trans people's experiences while neglecting to look at friendships across race and ethnicity or how racial and ethnic identity informs friendships. Overall, trans people as a group have more cisgender (cis) friends than trans friends and have more sexual minority friends than heterosexual friends. This finding supports previous research on cross-category friendships and suggests that a trans person (with the minority identity in the cross-category friendship) is the person within the friendship dyad who more frequently brings up identity-related differences with the more privileged person in the dyad (i.e., the person who is less oppressed in the trans–cis friendship dyad because of their cis identity). Trans people often bear the burden of initiating difficult gender identity–related conversations within their friend networks. Affiliation with the broader LGBTQIA+ community also affects friendships. Specifically, trans people who hold stronger affiliations with, and ties to, the broader LGBTQIA+ community have more trans friends, sexual minority friends, and friends who are also connected to the LGBTQIA+ community, as well as fewer heterosexual friends and fewer friends who are not connected to the LGBTQIA+ community.

Benefits and Drawbacks of Trans Friendships

Trans friendship research often focuses on the sexual orientation and gender identity of friends, the benefits and barriers within those friendships, and how trans people negotiate friendships. Looking at why trans people have friendships with other cis, heterosexual, trans, and LGBTQIA+ people enables specific benefits and barriers to friendships across these identity groups to be identified. Trans people seek out friendships with heterosexual and cis people because these friendships provide identity-based validation. These friendships are enjoyable because they often do not overemphasize trans experiences, and validation from heterosexual and cis people can be powerfully affirming. As the dominant group, heterosexual and cis people are perceived as being more stable emotionally and provide more opportunities for a larger number of friendships. Cis people help trans people to pass as cis, and friendships with heterosexual and cis people provide opportunities to educate cis people about trans identities. Yet, there are also barriers that negatively affect friendships between trans people and cis and heterosexual people because heterosexual and cis people often lack critical consciousness about issues related to sex, gender, and privilege. Heterosexual and cis people also sometimes use inappropriate language and struggle to talk about and understand trans experiences. Heterosexual and cis people might have less in common and fewer similar experiences with trans people, making maintaining the friendship more difficult.

When looking at motivations to have friendships with other trans and LGBTQIA+ people, specific benefits to friendships across these identity groups

can be identified. There are a variety of reasons to seek out friendships with other trans and LGBTQIA+ people, including a shared understanding of trans experiences and deeper knowledge of sex, gender, and privilege. Trans people also share similar experiences with other trans people, which offers an opportunity to speak authentically about being trans with open-minded and nonjudgmental friends. Friendships with other trans and LGBTQIA+ people provide a space to receive support, mentoring, and access to resources as well as a sense of belonging, community, and family. There are also barriers that negatively affect friendships between trans people and other trans or LGBTQIA+ people. Sometimes trans and LGBTQIA+ people invalidate trans identities and overemphasize gender identity and sexual orientation. Trans people fear being outed as trans, and these friendships can be fraught with interpersonal conflict.

There are also specific benefits of friendships with LGBTQIA+ people. For example, friendships with LGBTQIA+ people are beneficial because of the open-minded and nonjudgmental nature of the friendship. Friendships with LGBTQIA+ people offer a space for community support, a sense of belonging, and diverse perspectives and experiences. Friendships with LGBTQIA+ people can be used to educate others about trans lives and to find possible sexual partners. Yet, friendships can be negatively affected when LGBTQIA+ people lack a basic understanding of trans experiences or share too few similar experiences.

Finally, trans people identify specific benefits of friendships with other trans people. These friendships are beneficial because holding similar gender identities allows for authentic shared experiences, increased comfort with talking about trans experiences, and enhanced support, mentoring, and resources. Trans people also help other trans people pass as cis. One barrier that negatively affects relationships with other trans people includes the tendency for trans issues to dominate conversations. Trans people can experience negative friendships with other trans people that are characterized by high levels of conflict and emotions, as well as fears of being outed.

Specific benefits of trans friendships for cis individuals exist. Meaningful friendships with trans individuals can help cis individuals demonstrate less trans prejudice and more positive, trans-affirming behavioral intentions than do cis people who have no friendships with trans people.

Finally, disclosing a trans identity affects friendship. Disclosing a trans identity yields many different responses from friends, including affirming responses (i.e., acceptance), negative responses (i.e., questioning the validity of the trans identity), mixed responses (i.e., some friends may leave while others develop deeper relationships), and emotional responses (e.g., happy or indifferent). Disclosing a trans identity can also lead to strained or strengthened friend relationships.

Trans Men, Trans Women, and Nonbinary People

Differences exist in trans friendships across gender identity. Trans men, trans women, and nonbinary people all have distinct friendship patterns that suggest unique friendship needs exist within the trans community. Compared with trans women, trans men have more friends who are connected to the LGBTQIA+ community and more friends who are sexual minorities. Trans men also experience unique negotiations related to their identities as trans men within woman-identified cross-category friendships, particularly friendships with lesbians. Many trans men must come to terms with, and account for their masculinity within, these cross-gender friendships and also have to work to disown their privilege as men. Friendship research specific to trans women is quite limited and focuses on the identity of the friends with whom trans women have relationships. Trans women have more non-LGBTQIA+-affiliated friendships than their male counterparts. Nonbinary friendship research is also a new area of scholarly inquiry. Nonbinary people seem to have less distinct friendship patterns when compared with those of trans men and women. One area of distinction is that nonbinary people tend to have fewer non-LGBTQIA+-affiliated friendships than trans women do. Research on trans experiences that tease apart the differences between trans men, trans women, and nonbinary people is in its infancy. There is limited research on how friendships differ across gender identity, race, ethnicity, social class, or religious identity for trans people.

Microaggressions in Trans Friendships

A growing body of literature explores microaggressions committed in trans friendships. Trans microaggressions, or subtle intentional or unintentional forms of discrimination directed at trans people, are harmful no matter who commits them and are especially harmful when committed by a friend. Trans microaggressions are particularly harmful as they create ruptures within friendships, which is often the main source of social support for trans people. Often, the extent of the harm is based on the identities of the person committing the microaggression. Trans microaggressions are committed by cis, heterosexual, trans, and LGBTQIA+ friends but are most painful when committed by trans and LGBTQIA+ friends. Other research indicates that microaggressions experienced within friendships differ for trans men, trans women, and nonbinary people. Specifically, trans women experience microaggressions that they are not "real women," trans men experience microaggressions that they are not "real men," and nonbinary people experience microaggressions that they are not "really trans." These microaggressive experiences negatively affect friendships and have implications for positive trans identity development and well-being. Some emerging research has explored microaffirmations in trans relationships, but the impact of positive events in trans friendships is currently not well understood.

Future Trans Friendship Research

Friendships are important in the lives of trans people, who experience discrimination and prejudice on a daily basis and who might not receive support or care from family-of-origin members. The scholarship on trans friendships has primarily explored frequency and types of relationships across sexual orientation and gender identity, with some recent research exploring friendships for trans men, trans women, and nonbinary people. Friendships are important for trans people but are often stressful with respect to navigating conflict and lack of affirmation within the friendship. Literature on trans friendships has also primarily focused on white trans people as a monolithic group. More research is needed to explore how friendships manifest across different aspects of identity, specifically for trans people of color, trans people who are living in poverty, and trans people's experiences across cultures.

G

Garland, Jack Bee

Jack Garland was a trans man who lived and worked in late 19th-century and early 20th-century California. His mother was Eliza Garland, the daughter of Rice Garland, a Louisiana congressional representative, and his father was José Marcos Mugarrieta, the first Mexican consul to California. In the course of his life, Garland worked as a reporter in Stockton, California; served as an interpreter in the Spanish-American War; and became a Red Cross nurse following the 1906 San Francisco earthquake. At different times accepted and rejected because of his gender, his history has much to teach us about trans lives at the turn of the 20th century.

Childhood

Born in San Francisco on December 9, 1869, Garland grew up in a world where the anti-trans writings of the early sexologists were not yet shaping the city's understandings of sex and gender. Although assigned female at birth, Garland was known to be a masculine child, preferring tops and kites to dolls and enjoying the companionship of the neighborhood boys, yet his neighbors did not punish or pathologize this behavior. The family struggled economically; while his mother came from a wealthy family, his father seldom received a regular paycheck for his work as Mexican consul. Yet the family valued education, and once he reached his teen years, Garland was sent to a convent school for young women, where he acquired the writing and research skills that later allowed him to support himself as a reporter.

Young Adult Life

Garland's young adult life was one of loss and challenges. While in his teens, one of his brothers was sent to San Quentin on charges of theft and died of tuberculosis following his release. Then, when Jack was 17, his father died. Two years later, Garland was committed to the Insane Asylum of the State of California in Stockton. His stay there was brief; although he was sentenced by a judge for opium addiction, he was released 1 month later.

Following a brief stint in San Francisco, he returned to Stockton in his mid-20s, this time to live as a man: Babe Bean. Stockton was a small city of roughly 20,000 people, and its press took notice of the new resident, speculating about his sex. An accident with a horse carriage revealed that Bean had a traditionally feminine voice, and for the remainder of his stay, most people treated him as a masculine woman rather than as a man. Some even considered him a "freak," reflecting the growing influence of sexology and its pathologizing view of gender difference. After working for local newspapers for several months, he did gain the town's respect, yet the press continued to refer to him as a masculine woman.

Bean's earliest articles were about himself. The town was fascinated with his gender, and writing

about it gave him notoriety and enabled him to earn an income. But, in time, he was able to publish articles on events throughout the city, including a story on the insane asylum where he had been institutionalized as a youth. There he interviewed Spanish-speaking inmates, which raises questions about how he lived his ethnicity while in Stockton. His reporting offers a glimpse into how he publicly performed gender at this point in his life, as he referred to himself as the "first woman" allowed to visit some of the places he covered. Thus, it appears that, at the time, he did not identify strictly as a man.

Overseas Travels

By 1899, stories of battles and U.S. victories in Cuba and the Philippines were filling the pages of U.S. newspapers. Garland, like many young men of his time, was determined to join the effort. Traveling to the Philippines provided him with an opportunity to find adventure, and it afforded him the chance to once again be known just as a man. He secured a job as a mess-boy on an Army transport ship to Hawaii and then hid on the ship as it traveled to Manila. Following his discovery, he was accepted by the troops and obtained the same tattoo that they had. He worked as a translator and increasingly wanted to be known as "Jack," and when he returned to the United States, this time to settle in San Francisco, he lived as Jack Garland.

Later Life and Death

Following the Spanish-American War, Garland apparently stopped working as a reporter; at least his name ceased to appear on bylines. He was in San Francisco at the time of the 1906 earthquake and served as a nurse with the Red Cross and then briefly appeared in the Los Angeles press when he was suspected of being a spy. Garland had been arrested on a charge of impersonating a man, and he argued his innocence by reclaiming his identity as "Beebe Bean," one of the names he had used in Stockton.

In September 1936, he collapsed on a San Francisco street, suffering from an untreated ulcer, and died just short of his 67th birthday. It appears that he lived his last years among the poor and working-class people of the city, helping them to the best of his abilities, and his philanthropy was highlighted in his obituaries. So too was his sex assignment; for example, the death notice in the *San Francisco Chronicle* noted that "'Jack Bee' Was Woman." However, the fact that the press felt the need to forefront this aspect of his past suggests that Garland was by then living simply as a man.

The life of Jack Garland provides important insights into the experiences of trans people, especially mixed-race trans people, in the late 19th and early 20th centuries. While subjected to intense scrutiny and, at times, prejudice (which, for Garland, was compounded by his mixed-race heritage), trans people also could find acceptance and places where they might live authentic lives. Garland made a name for himself, both by being seen as gender different and by being thought of as simply "Jack."

Gatekeeping in the Transition Process

Gatekeeping within the transgender community is a term used to describe limiting or controlling access to medical interventions, such as hormone

therapy and gender-affirming surgery, based on select criteria that determine eligibility or ineligibility for such interventions. The "gatekeeping model" was historically used by mental health and medical providers to distinguish "true transsexuals" (the term used to describe transgender people at the time), who were deemed to be adequate candidates for medical interventions, from other transgender people who expressed interest in medically affirming interventions but did not meet set criteria required and thus were denied access to treatment. The gatekeeping model originated with the medical model of transgenderism in the early 1950s, and despite several changes in the implementation of gatekeeping, forms of this model continue to exist within the field of transgender health care.

Harry Benjamin was an endocrinologist and sexologist who is often credited for his pioneering work in the field of transgender medicine. In the 1950s, transgender people were viewed as having a mental illness that could only be treated by years of psychotherapy with the stated aim of increasing alignment between the person's gender identity and assigned sex at birth. In contrast, Benjamin believed that assisting transgender individuals in physical transition (i.e., social transition and medical transition) was the most appropriate course for treatment and began to develop clinical procedures with this aim in mind. Although Benjamin is often credited with increasing access to care for transgender individuals, his work also had the effect of constituting gatekeeping practices in transgender medicine. Eligibility for medical interventions at the time required extensive psychological evaluations, long-term psychotherapy (sometimes several years), early childhood history of cross-gender behaviors, the ability to "pass" (i.e., to be perceived by others as one's identified gender), and even participation in research studies. Historically, criteria for hormone therapy and surgery were also often predicated on sexual identity. For example, transgender women were more likely to be granted access to medically affirming interventions if they described themselves as attracted to cisgender men, thus being able to live within heterosexual norms posttransition. Shockingly, level of perceived attractiveness as one's identified gender was also at times used as part of gatekeeping criteria. Medical care under these circumstances excluded nonbinary identities, transgender people who did not experience dysphoria in childhood, transgender people who had queer sexual identities, and transgender people who did not sufficiently meet the cisgender expectations of gender presentation imposed by their medical providers. Transgender men were also often denied access to medical intervention, as clinical programs and researchers focused much more on the experiences of transgender women. Individuals who did not meet these specific criteria set by cisgender medical providers were denied access to care, while individuals who did meet specified criteria were completely reliant on their medical team for documentation to demonstrate that they met stated requirements in order to "open the gates" for desperately needed gender-affirming interventions.

The gatekeeping model of care was formalized in the first edition of the Standards of Care (SOC) published in 1979 by the Harry Benjamin International Gender Dysphoria Association, which is now known as the World Professional Association for Transgender Health (WPATH).

The standards outlined the need for transgender individuals to receive an official diagnosis of "transsexualism" as defined in the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition* (*DSM-III*) by a qualified mental health professional. The individual needed to receive psychotherapy for several months in order to be eligible for hormone therapy and even longer in order to be eligible for gender-affirming surgery. Additionally, transgender people were often only granted access to surgery if they had already started hormone therapy and if they were presenting in their identified gender role. Letters from more than one mental health provider were often required for medical interventions (and is still required in the case of genital surgery as outlined by SOC Version 7).

Although the current standards of care have shifted away from the requirement of psychotherapy and toward inclusion of an informed consent model, many transgender advocates and clinicians critique the current version of WPATH standards of care as maintaining the gatekeeper model. For example, the current standards maintain the need for an official diagnosis of gender dysphoria or gender incongruence, letters of referral, a specified amount of time living in one's gender role, and use of hormone therapy (unless not medically indicated)

in order to access genital affirmation surgery. It should be noted that these requirements also may prevent transgender individuals who are unable to access psychotherapy because they are uninsured, do not have access to mental health services, or experience barriers, such as childcare, inflexible work hours, or lack of access to transportation, that inhibit their ability to pursue psychotherapy, further enacting gatekeeping practices, albeit less intentionally. Transgender people of color, who are often in most need of care, are often those who are unable to obtain care due to the reasons described above.

Notably, despite the WPATH standards of care, many practitioners and clinics have shifted toward an informed consent model for hormone therapy (although referral letters continue to be required by surgeons in order to initiate any surgical procedure, and letters documenting a diagnosis of gender dysphoria are also required by insurance companies for reimbursement for any gender-affirming surgeries). The informed consent model is often contrasted with the gatekeeping model in transgender medicine. While the gatekeeping model assumes that a qualified professional is required to make a diagnosis of gender dysphoria and determine eligibility for any medical interventions the individual requires for treatment, the informed consent model places the autonomy on the individual. Informed consent requires the ability to evaluate for one's self the risks and benefits associated with a particular intervention. In this model, the provider (who may or may not be a mental health provider) works with the individual to assist them in making their own decisions regarding particular choices in their medical care. Thus, decision making is relegated to the individual. This model moves away from both the diagnosis of gender dysphoria and psychotherapy as a prerequisite for access to medical interventions (although it is still often discussed as an option with individuals who would like to pursue psychotherapy throughout their transition). Several major health care centers, colleges, community health clinics, and individual practitioners have begun to adopt the informed consent model of care. Given certain institutional constraints (e.g., documentation required for insurance companies, surgeons requiring referral from mental health providers), diagnosis of Gender Dysphoria and official letters from mental health providers are often still needed in order to access care; thus, aspects of the gatekeeping role, although lessened, remain embedded within this system.

Practitioners working within transgender health should be aware of the history of gatekeeping and the impact such a model of care has on transgender individuals and the community. Models emphasizing increased agency, informed consent, and a de-emphasis on gatekeeping practices provide a new model of care that focuses on access to care and the autonomy of transgender individuals.

Geek Culture

While geek culture has garnered the perception of being the domain of straight cisgender (cis) men, geekdom has long been a haven for marginalized people and particularly members of the larger LGBTQIA+ community. The LGBTQIA+ community's involvement in geek culture is perhaps not surprising, given how geek culture predominantly focuses on a passion for works of science fiction and fantasy stories that frame the "other," the overlooked, and the marginalized character as the protagonist of a story. Additionally, it provides a safe avenue for exploring allegorical themes and identities outside of the norm of a cisnormative and heteronormative society. Additionally, a comics convention (a large gathering of enthusiasts of a specific TV show, movie, genre, or medium such as *Star Trek* or video games, often referred to as a "comic con") is not altogether different from a LGBTQIA+ space, with comic cons often mirroring the LGBTQIA+ community's abilities to create safe spaces for expressions of love outside of societal norms. As a result, geek culture has long been a haven for transgender people to find community and representation of themselves outside of an exclusively LGBTQIA+ context.

Relationship Between Geek Culture and Trans People

When looking at geek culture, as with gender identities, it can be difficult to arrive at an all-encompassing definition by which to categorize and discuss the subculture as a whole. Geek culture encapsulates a wide variety of genres, artistic mediums, and levels of engagement. For example, fantasy and science fiction are universally considered "geek" subjects. However, so too are the entirety of the comic books and video game mediums, despite both including diverse genres beyond fantasy or science fiction. In a broad sense, one could simply define geekdom as a subculture of enthusiasts with a deep love of *obscure* media. Yet, with the explosion of science fiction and fantasy in mainstream culture during the early 21st century, growing out of the popularity of works from now-franchises like Marvel, *Star Wars*, *Dungeons and Dragons*, *Lord of the Rings*, *Harry Potter*, and *Star Trek*, as well as the expansion of comic and video game industries, geek culture has only grown less "obscure" as it enters mainstream consciousness. Geek culture, just like LGBTQIA+ communities, is also incredibly diverse, with it containing a seemingly endless number of distinctive niches and communities. In turn, scholars as well as those directly involved in geek culture often rely on the idea that "you know it when you see it."

Examining geek culture as a whole and in broad terms reveals that it contains core themes in common with trans experience. A notable shared feature between the two is the ability to look at humankind from a fresh perspective as a means of commenting on societal conventions with a forward-facing desire to redefine and broaden what it means to be human. Science fiction and fantasy rely heavily on the language of the ostensible outsider in order to comment on different aspects of the human experience—whether they be a superhero from another world trying to symbolize the best of ourselves, a schoolboy wizard fighting back against magical fascism (*Harry Potter*), an android who desires the ability to feel emotions (*Star Trek: The Next Generation*), a Hobbit who sets out to defeat evil not only in some distant dark tower but in the hearts of humankind (*Lord of the Rings*), or a human who boldly goes to alien societies that mirrors and extrapolates on an aspect of our own real-world society (*Star Trek*). It is not surprising that trans people, who are often cast as the outsider and whose mere existence challenges predominant societal norms of gender and sex, have found an affinity for, and safety in, geek spaces. Indeed, LGBTQIA+ audiences in general are more likely to choose horror or sci-fi as their favorite films than straight majority audiences. For many trans individuals, including nonbinary people, the parallels between the stories that form the basic "texts" of geek culture and their own experiences as trans people navigating a cisnormative world can be both uncanny and a source of personal strength.

Historical Perspective on Women and LGBTQIA+ Identities and Their Relationship to Geek Spaces

In the 20th and 21st centuries, geek culture has garnered the inaccurate perception as catering to a predominantly cis men following. This misconception has been perpetuated by numerous factors,

including but not limited to the how the mass mainstream marketing of genre works has been directed toward cis men as well as the elevation of cis men creators like J. R. R. Tolkien, Isaac Asimov, Gene Roddenberry, Stan Lee, and George Lucas into common household names.

While cis men have been influential as both creators and consumers, their predominance in the narrative of geek culture continually ignores that women, queer people, and trans people have been prominent members of geek communities since the beginning. While niche geek communities have existed previously, the coalescence of geek culture occurred in the 1960s and 1970s with the growth of the convention and fandom scene, which was spearheaded by women and LGBTQIA+ people, mainly driven by the rise of fandom for a small, cancelled, three-season show named *Star Trek*. The first major *Star Trek* convention, *Star Trek Lives!,* was run by Joan Winston and Elyse Pines, as well as several other men and women, and drew more than 3,000 people in 1972. The convention quickly expanded to nearly 15,000 in 1974, with 6,000 more having to be turned away. It is easy to connect these early conventions with today's geek culture being heavily convention oriented, with nearly every major city in the Western world having at least one, if not multiple, geek-focused conventions each year, hosting thousands of attendees (e.g., 2019's San Diego Comic-Con hosted 135,000 people). Indeed, LGBTQIA+ science fiction conventions like the annual Las Vegas Clexacon have garnered 4,000 attendees. These spaces often are the main hub for geeks to find and interact with each other, creating a yearly (or even more often) cultural event around which all other gatherings, groups, and events orbit.

Those who were unable to attend the growing movement of science fiction conventions in the early to late 1970s, either due to being unable to afford to attend or not living near a large city that hosted such an event, soon found their own distinct outlet for their fandom. Hundreds of *Star Trek* fanzines began to crop up during the 1970s as well, such as the prominent *Spockinalia*. A number of these fanzines were women led and devoted to fan fiction. This fan fiction also led to the rise of what is known as slash fiction, like *Kirk/Spock,* where two nonqueer fictional characters are written to be explicitly queer, often building off of (often unintentional) queer subtext in the original work.

Today, fan fiction is still dominated by women and trans writers. Prominent fan fiction database Archive of Our Own discovered that more of its users identified as genderqueer (6%) than as male (4%). With such a preponderance of trans creators, as well as women, working within this space, culture stereotypes streaming from transphobia, homophobia, and sexism often lead fan fiction to be simply dismissed as frivolous or uncreative. Sadly, this ignores the vibrant community of writers and editors making highly creative works of all skills and quality levels.

Another growing element of geek culture that remains dominated by trans as well as by cis women and LGBTQIA+ people is the cosplay community, or people who make elaborate costumes of their favorite characters across geekdoms. Cosplay often provides people an avenue to play in a new gender or identity, often creating a safe space for them to explore as exemplified by the subculture crossplay, where one dresses up in as a character whose gender differs from that of their assigned gender. Cosplay, as with science fiction in general, allows one to imagine a gendered (or agendered) existence outside of normative "human" categories, to imagine new possibilities that exist outside of societal pressures. As the cosplay and crossplay communities grew in the 1990s, they allowed for greater visibility and normalization of trans identities. As one crossplayer named Sarah pointed out in a 2015 article for the online news outlet *The Mary Sue,* "I went to that convention for another three years with my friends, and as I got more and more comfortable with the crossplayers I started to think more about trans issues and transitioning" (Figa, 2015). Many crossplayers found, especially as the community grew, that trans individuals were much more accepted. Certainly, if one can accept dressing up as a giant alien robot, being trans is not all that radical—perhaps it even becomes mundane! As another cosplayer states, "Not only did I not receive scrutiny or negativity, but I was far more openly encouraged . . . for perhaps the absolute first time since I started dressing, I felt fully comfortable" (Figa, 2015).

Transgender Representation in Geek Works

Transgender issues are not just limited to the communities around geek culture but within the works that fans themselves love. There has long been

explicit representation of trans topics and characters within Western geek fiction itself, often well before trans appeared in other genres. Prominent fantasy and science fiction writer Ursula K. LeGuin's popular 1969 feminist novel *The Left Hand of Darkness* features an alien race who have no fixed sex. Octavia E. Butler's book *Dawn* features an alien race with a third gender. *Star Trek: The Next Generation*'s 1992 episode "The Outcast" featured a trans guest character from an alien race, and later episodes in the franchise featured aliens with third genders as well as fleeting references to "transgendered species."

Sadly, however, trans themes are rarely used to directly discuss transgender issues or topics. Indeed, in many cases, trans themes or characters have been used to highlight other issues. For example, the aforementioned *Star Trek* episode used the transgender alien character, who was a member of a nonbinary alien race, to enable a discussion of gay rights. While this certainly was well intentioned and arguably had the desired informing effect on its audience, it also signals the common conflation of sexuality and gender issues. It also highlighted the writer's ignorance of the fact that being nonbinary, or without gender, is not something relegated only to fictional alien species but something that real-life humans can be as well. This is not an isolated trend, with numerous real-world trans identities consistently being depicted as aliens, robots, or other nonhuman entities used to discuss other issues. For example, the television sitcom *The Good Place* featured Janet, a female-presenting nonbinary artificial intelligence who was used to discuss issues of moral philosophy rather than have any of the actual human characters within the narrative simply be nonbinary as well. This often has the side effect, intentional or not, of literally dehumanizing trans people, and further denormalizing their existence within real-world spaces.

It would be remiss, however, to deny the importance of these trans representations to the trans community, even despite their flaws. Trans fans often find great affinity in these characters, as illustrated by one trans fan who fell in love with the alien race Trill, a species capable of reincarnation in different genders, in the *Star Trek* franchise. As one trans Trekkie stated,

> "There's so little canon LGBT+ content in general, let alone transgender-specific content, because a lot of it has been censored and banned throughout history, that sometimes we have to resort to queer theory to find characters that represent us. Whether it is good representation or not, no one can deny that many of the Trill characters we've seen in the show have experiences that partially line up with transgender people in a way that makes them partially representative of the transgender experience." (Coates, 2019)

One can also argue that by representing trans issues as metaphorical makes them "more palatable" to an audience who might normally be hostile to more explicit representations of trans issues and thus open them up to understanding trans people in the future. In the end, it is impossible to fully quantify metaphorical trans representation as wholly good or bad.

With growing modern awareness of trans identities, the advancement of LGBTQIA+ inclusion in creative spaces, and the mainstream explosion of fantasy and science fiction content, trans representation has continued to increase and, as a result, become more explicit. Recently, author N. K. Jemisin also featured a trans character in her *Broken Earth* trilogy, which set a record for being the first series to win the Hugo Award 3 years in a row. Comic books have vastly expanded trans representation, with *Saga* and *Bitch Planet* being prominent examples. Similarly, on television, DC Comics–focused series have often led the way for LGBTQIA+ representation on television, with trans woman superhero Dreamer as a regular on *Supergirl*, and *Titans* featuring a deaf trans man character in Season 2. Numerous geek TV shows like *Sense8, The Chilling Adventures of Sabrina, She-Ra and the Princesses of Power,* and *Doctor Who* have all featured trans characters. Video games have also begun to feature more explicit trans representation, with *Assassin's Creed* and *Persona* being prominent examples. In 2019, during a premiere Microsoft Xbox event, video game developer DONTNOD announced their new game *Tell Me Why* would feature a trans man protagonist, signaling the growing desire for trans stories within the still nascent video game industry, which had until the 2010s mainly focused on white cis men characters or cis women, like Lara "Tomb Raider" Croft, who were heavily influenced by a male gaze.

These positive developments unfortunately do not mean the issues of past representations have completely disappeared with geek culture, as trans themes and characters are still predominantly presented as metaphorical or nonhuman. For example, *Borderlands 3,* one of 2019's top-selling video games, featured a playable android character who was treated as nonbinary by both the in-game world and, perhaps more notably, the game's real-world marketing team. As more definitive representations continue to increase, these explorations of gender through metaphors tend to feel more understandable. Certainly, there is a necessity and ability for both metaphorical discussions of gender as well as more explicit ones to coexist within geek and mainstream culture, as both offer opportunities for unique perspectives on the subject.

Anti-Transgender Reactions and Challenges

Although geek communities have been a haven for trans individuals within popular culture, they have not been completely immune from larger systems of transphobia and femmephobia. Trans and cis women are often demanded to legitimize their fandom within geek communities. Indeed, geek communities have a long history of gatekeeping, or placing arbitrary measurements of what it means to belong to said community. Many groups tend to place an emphasis on knowledge of obscure minutiae within specific fandoms, such as knowing airdates of specific episodes or the names of certain aliens that appeared in single episodes, and often will "quiz" members of the geek community to prove their fandom, despite fandom's being more about intense love of a specific work of fiction, not simply accrued knowledge. These arbitrary measurements are often disproportionately leveled at anyone who is not a cis man, as it is incorrectly believed that trans and cis women identities could not possibly be interested in geek topics.

Indeed, sometimes cis men–dominated groups within geek culture act to create the perception of a "fake geek girl," believing that trans women are only pretending to like geek culture in order to appear more attractive to men. This closely mirrors the same stigma that trans women face when they are falsely accused of only being gay men pretending to be women in order to trick straight men into emotional or physical relationships. This inaccurate concept stems from the belief that men are the sole predominant force within a geek community.

Sadly, the sense of ownership over geek space by cis men has led to the modern development of toxic fandoms. "Toxic fans" demand that only their vision of geek community or fandom is worthwhile and therefore seek to push other identities, often non-cis white men, out of geek spaces. With the rise of diversity within both public geek spaces and within fandom works in general, toxic fans often end up harassing, doxxing, or otherwise abusing others. For example, Vietnamese American actress Kelly Marie Tran, who starred in the film *Star Wars: The Last Jedi* in 2017, was forced off social media platforms after being the target of a harassment campaign that saw her as part of a presumed "forced diversity agenda" by the Disney Corporation (which owns the *Star Wars* franchise) to push out cis white men, who had hitherto been the main featured protagonists of *Star Wars* films. Such arguments of a secret agenda by mega-corporations to force diversity or "popular feminism" onto mass audiences often fall into rhetorical arguments like those of other popular conspiracy theories, with toxic fans relying on the repetition of false rumors and unresearched facts to create a feedback loop of content reinforcing their beliefs that they, as cis white men, are under attack. The trans creator behind the sci-fi comic book and TV series *Vagrant Queen,* Magdalene Visaggio, also faced a similar threats and abuses from within the online geek community. Women, people of color, and LGBTQIA+ people who are prominent in geek communities on social media often face similar harassment campaigns generated by toxic fans.

Finally, the trans community has also been met with pushback from actual creators of geek works themselves. For example, in 2019, *Harry Potter* author J. K. Rowling posted on Twitter in support of Maya Forstater, a U.K. woman who had lost a court case after being fired from her job for anti-transgender rhetoric. Rowling's tweet sent reverberations throughout the *Harry Potter* fan community, which included numerous LGBTQIA+ people and allies. *Harry Potter* focuses on allegorical themes of fighting back against the demonization of the other as well as how language can be used to dehumanize marginalized groups. As a result, trans fans were left having to analyze how

to incorporate Rowling's incongruous stance against their identities with their relationship with *Harry Potter,* a series that represented a formative experience for an entire generation of millennials. While J. K. Rowling's anti-transgender stance is perhaps the most prominent example, there have been several notable geek creators, such as *Doctor Who* writer Gareth Roberts and *Ender's Game* creator Orson Scott Card, who have expressed anti-transgender views despite creating works that trans fans find connection within. As a result, trans fans are left to wrestle with a contentious relationship between an artistic work and community that speaks to them and the damaging viewpoints of those work's creators. Some have chosen to leave the fandom, while others have decided to ignore an author in favor of the love of a work or community surrounding said work.

Contemporary Representation and Future Directions

Unfortunately, owing to a misconstrued belief that centering trans or any LGBTQIA+ stories could negatively affect revenue, major motion pictures, often expensive and "risky" artistic endeavors, still rarely feature major trans characters except for very minor roles in films such as *Spider-Man: Far From Home,* where one of the middle school superhero's barely seen classmates was trans. Of course, while explicit trans representation has steadily increased, it still has a long way to go, as evidenced by the 2019 GLAAD Studio Responsibility Index, GLAAD's yearly researched analysis of LGBTQIA+ representation in television and film. In 2019, there were only 38 trans characters on TV, with only 5 being nonbinary. Additionally, the effectiveness and accuracy with which the trans themes or characters are portrayed in any work vary in quality, even when done with the best of intentions by the creators. While *Sense8* includes a nuanced depiction of a trans character, other shows like *The Chilling Adventures of Sabrina* have left much to be desired due to muddled and confusing development of the show's trans character of Theo, who has alternatively been depicted as nonbinary and as a trans man. Although a trans human may oscillate between identifications within their lifetime, Theo's vacillating gender depiction seems to stem more from the writers' uncertainty with what to do with the character, as well as misunderstandings of a trans identity. So, while trans representation continues to expand in popular culture, there are certainly more discussions to be had and battles to be fought.

Ultimately, it is difficult to encompass the vast diversity and breadth found within geek culture and how it speaks to trans people. In many ways, this complexity reflects the trans experience in and of itself: a diverse group of people who find community through shared narratives and issues of how they relate to their own as well as societal expectations of gender. Similarly, although geek culture may encompass everyone from a devout Trekkie, to a board game creator, to a video game streamer, they are all bound by a distinct feeling of broader community through a love of an artistic endeavor that speaks to how they define themselves.

Gender Affirmative Model

The gender affirmative model is a structure of care for gender-expansive and trans individuals that evolved in the first two decades of the 21st century. Although it originally was crafted by a consortium of individuals from different disciplines across the globe who focused their work on children and adolescents, the model itself applies to people of all ages.

Contours and History of the Gender Affirmative Model

The overarching global principle of the gender affirmative model is that every individual should have the right to live in the gender that is most authentic to them. This principle is informed by the evidence-based studies demonstrating that attempting to change or contort a person's gender does harm. In the model, gender health is defined as the opportunity for an individual to live in their authentic gender with social support and freedom from aspersion, rejection, or manipulation. The major tenets of the gender affirmative model are as follows: (1) Gender variations are not disorders; there are infinite pathways of gender; cisgender is only one of many; each gender pathway is positive; no one pathway is privileged over another. (2) Gender presentations are diverse and varied across cultures, requiring cultural sensitivity. (3) Gender involves an interweaving of biology, development and socialization, and culture and context. (4) Gender may be fluid and can be nonbinary. (5) Gender is not fixed at a moment in time but is a lifelong process. (6) Co-occurring psychological issues, if present at all, are typically related to interpersonal and cultural reactions to an individual, not internal psychopathology. (7) Therefore, pathology more likely lies in the culture rather than in the individual.

Beginning in the first decade of the 21st century, professionals and community members involved in crafting the gender affirmative model took on the task of relearning gender and developing new developmental guidelines that more accurately reflect the realities of children of all genders, rather than pertaining only to individuals who abide by gender in two binary boxes—male and female, determined by the sex designated at birth. The gender affirmative model recognizes that knowledge comes not just from scientific studies and intellectual formulas but also in the lived experience of the individuals who find themselves outside the traditional binary gender boxes. The difference between sex (a biological designation at birth), gender identity (who I am—male, female, or other), and gender expressions (the way I like to "do" my gender—mode of dress, appearance, movement, choice of activities, and so forth) was carefully delineated. Furthermore, the separation between gender identity and sexual identity was underlined, a task that felt essential as so many people continue to conflate the two. Sexuality and sexual orientation identity (e.g., gay, bisexual, heterosexual) have to do with many things, but at their center is the object of desire—do we desire people who are the same gender as us or a different gender from us, people of any gender, people of fluidly defined gender, people who are trans, or people of no declared gender? Our gender identity and expression, on the other hand, have to do with how we incorporate our own culture's definitions about being male or female with our own internal preferences, desires, and recognition of who we are as a boy/man, a girl/woman, a third gender, a fourth gender, gender nonbinary, and so on.

In practicing the gender affirmative model, professionals and laypeople alike are advised as follows: When it comes to knowing someone's gender, it is not for us to say but for the individual to tell. It will not necessarily be known by looking at the sex designation on the person's birth records or at the person's body or how the person dresses or moves. It is a core psychological piece of oneself, albeit shaped by others and influenced by the body one lives in, but transcendent of that as well. It may show itself to the outside world, or it may be hidden. Within the rubric of listening, not telling, the role of the health or mental health professional is to facilitate a child's discovering and living in their authentic gender with adequate social supports.

Here is an example of the necessary listening process. Little Sammy tells his mother, "Mommy, I want a Barbie doll and I'm a girl." His mother, guided by her own feminist principles, replies, "Sammy, you don't have to be a girl to play with a Barbie doll. Anyone can play with a Barbie doll. You're a boy. And yes, of course you can have one." Sammy bursts into tears and collapses on the floor, asserting, "Mommy, I *know* boys can play with Barbie dolls. That's not what I said. I said I'm a *girl* and I want a Barbie doll." With good intentions, Sammy's mother told Sammy who she thought Sammy was rather than listening to Sammy make his first foray into telling his mother who he really is—a girl.

Comparison With the Two Other Major Models of Gender Care

When considering children and adolescents, the gender affirmative model is best understood when compared with the other two prominent models of care—the reparative or conversion model and the watchful waiting model. The reparative model of care involves interventions to lead a person away from a transgender outcome. It has typically been applied to boys deemed "effeminate" by the social environment. Both Richard Green and Kenneth Zucker have been identified as practitioners following a reparative mode of treatment with gender-expansive children, with Dr. Zucker's model known as the "living in your own skin" model. In the watchful waiting model, developed by the pioneering group of gender experts in the Netherlands and often referred to as the "Dutch model," children who articulate either a trans identity or gender-expansive expressions are asked to wait until adolescence to engage in any social or medical transitions, while given free rein for gender exploration in circumscribed situations prior to that. The gender affirmative model grew out of and away from the Dutch model and has always been in opposition to reparative models of care.

The gender affirmative model, in response to the watchful waiting model, operates from a premise of stages, not ages. This translates to mean that whenever a child is clear about their asserted gender identity, whether at age 3 or age 15, they should not be held back from living fully in that identity, as long as they have the support of their parents and it is safe to do so in the social-cultural context in which they live. The support would include parental consent for both social and medical gender transitions, when appropriate. In no circumstance should any child be shaped or manipulated to move away from their authentic gender to one that is more socially acceptable to others but not in accordance with who that child is. The gender affirmative approach is the most recent of three major models of gender outlined above and by the end of the second decade of the 21st century had become the ascending international guideline for supporting individuals' gender health, in accordance with international human rights declarations regarding the health and well-being of trans and gender-expansive individuals.

The Gender Affirmative Model: Application, Support, and Opposition

The gender affirmative model is designed to be applicable to parents raising a gender-expansive or trans child, families with a gender-expansive or trans adult family member, and gender-expansive/trans individuals themselves, along with the host of interdisciplinary professionals engaging in promoting gender health. This would include educators, pediatricians, primary care doctors, nurse practitioners, endocrinologists, health educators, mental health professionals, public health officials, clergy and religious leaders, attorneys, judges, and policy makers. In essence, the gender affirmative model is seen as a community affair, one that takes a village to ensure that all who live in that village have the

opportunity to achieve optimal gender health. It is commonly associated with a medical model of care, often housed in medical centers or community clinics, in which individuals can seek medical interventions to consolidate their gender identity, including puberty suppression, gender-affirming hormones, and surgical interventions.

The World Professional Association for Transgender Health (WPATH), the most prominent international organization addressing the needs and establishing the standards of care for gender-exploring, trans individuals of all ages, adopts the gender affirmative model as its organizing schema. Other professional organizations, such as the American Psychological Association and the Pediatric Endocrine Society, have also endorsed the main tenets of the gender affirmative model.

The basic tenets of the gender affirmative model were collated in a publication in 2013, "The Gender Affirmative Model: What We Know and What We Hope to Learn," coauthored by a group of medical and mental health professionals, who were involved in the first U.S. longitudinal study of youth receiving medical interventions as part of the consolidation of their gender, and representing each of the first four pediatric gender clinics in the United States. Six years after the publication of this influential article, the number of gender clinics adopting the gender affirmative model of care had grown to over 50 in the United States alone.

There are some who are adamantly opposed to the gender affirmative model. Those strong critics are overrepresented in conservative and evangelical religious groups. For example, Michelle Cretella, president of the conservative organization American College of Pediatricians (ACP; not to be confused with the largest U.S. professional organization of pediatricians, American Academy of Pediatrics, or AAP), critiqued the model as a group of institutions that push children to impersonate the "opposite sex," offering them puberty blockers and cross-gender hormones, sterilizing them, and removing healthy body parts, all with accompanying untoward psychological damage. Dr. Cretella concluded that these harms constituted institutionalized child abuse. It should be noted that the Southern Poverty Law Center has labeled the ACP an anti-LGBTQ hate group that promotes false claims and misleading scientific reports.

The Gender Affirmative Model: Dispelling Myths and Deepening Roots

Myths abound that followers of the gender affirmative model have an agenda to make people trans and are driven by political ideology rather than evidence-based scientifically sound practices. In reality, the goal of gender affirmative providers is simply to help get an individual's authentic gender in focus and support that individual in being able to live fully in that gender. Where circumstances exist that make it impossible or risky to exercise that right, the gender affirmative model does endorse advocacy to build a more gender-inclusive environment wherever possible. Such activities include change at a social level, with a call to professionals to step out of their individual offices to create that change. The call is not ideologically driven but based on the growing body of scientific evidence that gender-expansive and trans individuals, both children and adults, have better mental health outcomes when they receive positive social supports from their environment and compromised mental health, including serious risk factors such as self-harm or suicidality, in the absence of such support.

Those involved in designing and practicing the gender affirmative model also recognize that it is a model that must be understood in social context and with the recognition that the model will shift as historical circumstances change. As one example of this, when Colt Keo-Meier and Diane Ehrensaft worked on the revisions of their manuscript drafts for their 2018 publication, *The Gender Affirmative Model,* they found that they had to go through the entire volume three different times in that many years to update the terminology to adhere to the fast-moving changes in "appropriate" gender terms—for example, from *gender variant* to *gender nonconforming* to *gender expansive* to *gender diverse*. It is widely acknowledged that the gender affirmative model is a nonstatic entity, as articulated in the final pages of *The Gender Affirmative Model,* in which the reader is reminded that just as each child's gender is an interweaving of nature, nurture, and culture over time, so too do our models of care evolve over time, with shifts in the culture, more scientific discoveries of nature's contribution to gender development, and each of us differently nurtured over time in our own gendered selves. With that said, we must continually leave

room for alterations in the gender affirmative model to meet the evolving tapestries of gender—work that we creatively hope will never be done.

Gender Binaries

Western societies compress infinite human identities into fixed categories, many of which are constructed as binaries. Examples of such binaries include sexual orientation (heterosexual/homosexual), race (white/person of color), sex (male/female), and gender (man/woman). By their very nature, binary constructs offer two mutually exclusive possible ways of being. Binaries limit choices to only two possible options and typically create a hierarchy in which one category is viewed as "better" than the other category. This hierarchical order is embedded in societal systems and works in concert with systems of oppression, thereby upholding power and privilege and perpetuating a social order that is rooted in racism, sexism, cis/heterosexism, and patriarchy. Not only is the maintenance of this social order limiting, but it also perpetuates violence and marginalization. Perhaps the most pervasive example of a constructed binary is the one for gender—the idea that there are two, rigidly "bounded" gender categories, each with an accompanying set of social and behavioral roles and expectations. The binary classification of gender, rooted in colonialism and predicated on the power of white, European, male dominance, is a foundational element of Western societal structures. This entry, which is focused on the United States, explores both the sex and gender binaries and examines the ways in which binary classifications of gender produce and maintain violence against and marginalization of trans people.

The Sex Binary

The reliance on the sex binary has been reinforced by the medical field and exemplified by the history of performing unnecessary surgeries on intersex children to alter their bodies in such a way that they can be classified within the sex binary. Intersex people are individuals born with variations in sex characteristics, including chromosomes, gonads, sex hormones, or genitals that do not fit the typical definitions of a male or female body. Research has shown that there is no single biological measure by which every human can unassailably be placed into one of two categories—male or female. However, many institutions and the people within them still think of sex as a binary. For instance, binary sex categories structure how individuals behave, engage, and interact within public facilities, the criminal legal system, homelessness services, education, and health care, to name a few. For instance, determinations regarding which medical procedures are covered by health insurance frequently rely on a sex designation as male or female, such as a prostate exam or Pap smear. This puts health insurance administrators in a position to approve or deny claims based on the body parts they associate with male and female bodies.

The Gender Binary

The *gender binary* refers to the pervasive idea that there are two, and only two, rigidly bounded and dichotomous genders: man and woman. The gender binary is often believed to correspond with the sex binary: female = woman and male = man. In

this way, the binary system of gender classification assumes biological determination and stability over time. The sex of a newborn is most often determined by a cursory glance at their genitalia, which then is used to infer their gender and, subsequently, the accompanying social norms, roles, and actions for that gender categorization. There are even ultrasound tests, often followed by "gender reveal" parties, for those who are unable to tolerate the ambiguity of not knowing their unborn child's sex.

Cisnormative Social Institutions

The sex and gender binaries, which often act in concert with a binary construction of sexuality, produce cisnormative social systems that routinely presume a cisgender identity and disregard identities that exist outside of the gender binary. Thus, using a binary classification of gender as a way to organize a society creates functional challenges for many trans individuals within related social systems and structures. From completing paperwork to navigating sex-segregated spaces to ensuring access to health care, there is quite literally no space for trans individuals, no box for them to check, no place for them to exist.

Individual Challenges Related to the Gender Binary

The idea that gender is binary harms individual people because this notion stigmatizes traits, behaviors, and identities that diverge from what is considered typical. Individuals who exist in between or outside of binary categories are located outside of that which is recognizable, and thus "knowable," to the organizing systems of contemporary society and the individuals within them. Dominant structures of knowledge and power are directly challenged through the act of existing in between or outside of the gender binary. Consequently, people whose gender is not easily discernible, or who are not easily located within binary gender categories, pose a threat to the social order of white, capitalist, cis, heterosexual, male dominance. This perceived threat may drive individual people, the institutions they create, and the structures they uphold toward active erasure ("if I don't know, it does not exist") while challenging the idea that there exists an essentialized truth about gender identity, gender expression, and gender roles. The marginalization of, and violence perpetrated against, trans people is partially, if not entirely, the result of this perceived threat.

There are many people for whom this binary system of gender categorization works, including many trans people. For example, some trans people experience congruence with the gender binary, strongly identifying with the category of woman or man. Identifying within the gender binary is not in and of itself the problem. Problems arise when a binary classification of gender is imposed and/or presumed and when binary gender categorization is a prerequisite for access to and acceptance within many public institutions. For instance, when seeking emergency housing services that are segregated according to a binary system of gender, individuals who are nonbinary must choose a binary gender category, or they may be assigned a binary gender category based on their identification documents. Without complying with the binary in this instance, an individual would not have access to emergency housing services. The same is true within some religious institutions, where different types of services and spiritual rituals are conducted separately for women and for men. Sometimes even the institutions of marriage and the family exclude family members who do not identify within the gender binary, evidenced by trans people who have been ostracized by their families of origin.

Structural Challenges Related to the Gender Binary

The system of U.S. governance, which comprises laws, policies, language, and power, is predicated on a binary notion of sex and gender, and many aspects of public policy are contingent upon one's sex classification. In 2020, under the Trump administration, the U.S. Department of Health and Human Services issued a regulation eliminating protections for trans people against discrimination in health care systems, including discrimination from medical professionals, health insurance companies, and hospitals. This regulation and other Trump-era policies in the areas of housing, education, and employment narrowed the legal definition of sex to a biologically determined, immutable trait that is stable over time, and thereby sought to remove trans people from the definition of "sex discrimination."

However, in 2020, the Supreme Court ruled that trans people are included in "sex discrimination" under federal employment law, and in 2021, the Biden administration extended this trans-inclusive understanding of "sex discrimination" to federal laws in housing, education, and health care.

Public policy can also challenge a trans individual's very personhood and their legal recognition as a member of society. For example, legal recognition as an individual person, with rights and equal protection under the law, often depends upon a binary classification of sex (m/f)/gender (m/w). These binary sex/gender classifications are assigned at birth, documented on a birth certificate, and recorded within state Departments of Vital Records and the federal Social Security Administration. These records are used to obtain government-issued identification documents, such as a driver's license, state ID, and passport. The rules regarding amendment of these documents vary from state to state. Gender-confirming surgeries are a prerequisite for identification document amendments in some states, which excludes many trans people who either cannot or do not wish to undergo such procedures. Some states require an individual to obtain a court order before updating their identification documents. The United States does not have a nationally recognized option for categorizing and documenting an individual's gender outside of the sex/gender binary.

Public policy codifies the unequal treatment of trans people along raced, gendered, sexualized, and classed lines—people who are already hyper-policed and targeted in a way that severely restricts their ability to fully participate in public life. For instance, New York State law includes the "Loitering for the Purpose of Prostitution" law, commonly referred to as "Walking While Trans." This law has resulted in the profiling of trans people, particularly trans people who are Black and Latinx women. Additionally, beginning in the 2010s, legislation has been introduced at state and local levels that restrict access to public restrooms and other sex-segregated facilities. School districts have also proposed policies limiting the ability of trans students to participate in sports or to authentically engage in gendered school-based social rituals such as school dances, as well as homecoming courts and proms during which a queen and king are elected by the student body. Exclusionary policies allow trans people to be discriminated against in health care systems, create barriers to obtaining identification documents that reflect an individual's accurate name and gender, and authorize discrimination against trans people under the cloak of religious freedom.

These policies codify the "othering" of trans people such that discrimination, victimization, and marginalization are considered not only as socially acceptable but even as necessary for the "safety" of the whole. The binary classification and associated roles are so clearly defined that anyone not conforming is met with suspicion and seen as a threat to the cisnormative social order that the gender binary and corollary heteronormative social roles are designed to maintain. Exclusionary policies, rooted in binary gender classification, communicate that people in positions of power are not only justified in policing the gender of others but that doing so is a public responsibility. This public responsibility is then further enacted by individual people, including family members, teachers, social service workers, police officers, and others who interact with the public on a daily basis.

Gender Clinics in the United States

For gender transition in the United States prior to World War II, documentation of clinical care is limited; at that time, European clinics, predominantly in Germany, were still defining the medical procedures and expectations for care. The early 1940s show some Americans traveling to Germany for surgery, a few U.S. doctors in Chicago and California beginning to provide hormonal care, and at least one court case petitioning the Supreme Court of California for a legal name change for gender transition reasons. As in Europe, gender transitions of the pre–World War II era were viewed as medical interventions for people with intersex conditions, who were sometimes referred to as "inverts," meaning the physical body was of one sex but the psychology and mind were of another.

After World War II, doctors in the United States began to support gender transition care using hormones, a method refined largely by the pioneering work of Harry Benjamin in New York and San Francisco. Some individuals would seek complementary surgical care abroad before surgical care became available in the United States in the 1960s. This predominant focus on endocrinology as an initial pathway for gender affirmation, with or without surgeries, has continued for the next six decades in the United States.

Community Collaborations

Early systems of care were developed in collaboration with community organizations and members: Harry Benjamin credits Christine Jorgenson (a woman whose 1952 trip to Denmark for vaginoplasty was highly publicized) with funding the vast majority of his early studies. Grassroots organizations to support trans persons in the United States began to develop in the post–World War II era and set a model for the hundreds of currently existing trans-focused community advocacy, legal, and clinical care support groups in the United States (e.g., National Center for Transgender Equality, TNet, Gender Spectrum). Coordinated efforts by trans communities and allies have contributed to a system of clinical care that includes multiple forms of seeking care to meet the many diverse needs of individuals seeking gender affirmation services.

Currently, many providers support youth and adult gender care services split by type of care (hormonal, psychological support, surgical preparation). Adults and youth may seek hormonal care within the context of a primary care provider, gynecological care, or in a clinic that provides broad-based health services to LGBTQ persons. Most major U.S. cities also offer low-cost or sliding-scale shot clinics that provide gender-affirming hormones. The diverse forms of seeking care available in the United States stem from the longstanding collaboration, and sometimes tension, between medical providers and community members. The system of community-informed, collaborative care models has been retained, and trans communities remain an active component of treatment protocol development.

Finances and Insurance

In the United States, care systems vary considerably by locality, and gender-affirming medical care is often funded by the individual and occasionally by third-party insurers or government systems. Prior to the Affordable Care Act (ACA, passed in 2010, enacted in 2013), around 16% of persons in the United States were living without health insurance, and those were disproportionately likely to be trans. Furthermore, most insurance companies of that time covered little or no component of gender affirmation care. The ACA cut in half the number of uninsured people and mandated coverage of some gender-affirming services, if criteria were met. There have been continuing legal challenges to care coverage for trans persons, which contributes to the ongoing dynamic of a care system that evolves to meet the needs of a constantly changing environment and includes both social and legal push from community members and medical personnel.

Some adult clinics function in an integrated manner, but many individuals do see separate sets of providers for things like hormonal and psychological care. Services such as name change support, housing support, and other antidiscrimination support may be provided in the same context that provides HIV testing and hormonal care. Currently, at least 45 distinct community-based treatment centers advertise varying constellations of medical transgender support services. Services provided included trans-positive primary care, behavioral health support, gynecological services, hormones, HIV support, and family planning. In some cases, centers also offer support for victims of violence, a name change clinic, acupuncture services, and hair removal services. Most do not provide surgical services but may refer to outside clinicians and provide preoperative and postoperative care. Some individuals continue to travel for surgical care to a country that allows nonresidents to seek surgery at a price cheaper than what is available in the United States. Both Thailand and Belgium currently accept nonresidents for surgical gender reassignment procedures.

Coupled with the U.S. medical system, which does not provide insurance for all people and allows insurance to limit or deny coverage of some or all gender-affirming care, the U.S. clinical care model has developed into a quite decentralized system of providers focused on hormonal care and a considerably smaller number of surgical providers who may or may not work closely with medical hormone providers and psychological teams.

Gender Clinics Outside the United States

Outside the United States, efforts to medically alter sex originated with surgical experiments on animals in the early 1900s. Some individuals (then labeled "inverts") were at that time requesting and receiving surgeries for removal of testicles, breasts, or uteri. The Institute of Sexual Science in Berlin developed and offered what was then called gender reassignment surgery (GRS) up until May 1933, when it was looted by the National Socialist Party police and Nazi student groups. There are a few reports of continuing surgeries in Europe (namely, Norway and Denmark) during World War II, but more commonly, gender-diverse persons were prosecuted and subjected to experimentation under Nazi rule. After the war, clinics outside Germany moved to prominence in providing GRS, and developments in the use of hormones broadened the scope of gender-affirming interventions available. Throughout the 1940s, interventions began to include legal alterations in name or sex, and it was increasingly understood that sex transition was an element of one's identity, or sense of self, rather than simply a feature of sexuality.

A number of non-European countries also served historically important roles in providing GRS, including a French-run clinic in Casablanca, Morocco, which provided vaginoplasty from the 1950s to the 1980s, serving thousands of individuals. Programs in Thailand began to offer surgical interventions in 1975. Although initially these surgical interventions were provided mainly to Thai people, by 2012, over 90% of people receiving surgeries in Thailand were not Thai. International, non-European clinics served an important function in providing surgical care for people who may otherwise have trouble accessing surgery in their home country due to availability, cost, or regulations.

Clinics across Europe and in Australia and Canada have continued to develop as integrated programs with team-centered systems of care. Integrated gender clinics often have coordinated care with psychologists, surgeons, endocrinologists, and sometimes other specialists (aestheticians, speech and language therapists, etc.). In countries with centralized medical care systems that provide coverage for transgender health care, integrated clinics are an efficient way to ensure that people's needs are met and all services are managed with communication across providers. Notably, clinics in the Netherlands, United Kingdom, Canada, and Belgium have played active roles in developing standards of care for trans persons worldwide. Depending on how health care is managed, each country has a slightly different way of organizing gender-affirming care. Integrated clinics appear to be common, however, throughout countries with socialized medical structures (Europe, Cuba, and parts of South America). In countries where medical structures are fee-for-service, gender services tend to be less integrated (e.g., the United States, Thailand).

Given the divergent evolution of services in international contexts that have focused on surgery, it is not surprising that gender-affirming services today tend to integrate surgery alongside other types of affirming care such as hormone therapy or psychological support. In contexts where medical and psychological care are covered through nationalized insurance programs, as in much of Western Europe, Australia, Canada, and some Asian countries, clinics have developed that provide assessment and diagnosis, as well as hormonal, psychological, and surgical care, all in one integrated system. In most of these countries, as well as many others throughout the world, treatment for gender dysphoria is covered by medical insurance, and treatment decisions are made collaboratively with an individual and a team of treatment providers. At the time of writing, dozens of clinics worldwide provide different constellations of gender-related care. Some clinics provide services that are accessible only for those living in that country and as such may have a low profile internationally, such as those in Cuba and Iran. Some clinics are more surgically specific and cater to international "medical tourists," like the multiple clinics in Thailand. European, Canadian, and Australian clinics offer far more comprehensive services, including psychological support, hormone therapy, individual and group therapy, and HIV support, and some even provide speech and language therapy and body hair removal.

Gender Creative

Individuals who have stepped out of the gender-binary boxes of male–female in identity, expressions,

or both have had to develop innovative, individualized ways to consolidate their gender selves and craft expansive notions of gender, either on their own or collectively. "Gender creative" is an adjective phrase that describes both those individuals themselves and the activities they engage in to establish a more gender-inclusive environment. This entry elaborates on the origins of the term, its common usage, and its influence on contemporary understandings of gender development.

Gender creative is a term coined by Diane Ehrensaft and first described in detail in her 2011 book, *Gender Born, Gender Made*. By definition, it is an adjective to describe the developmental position in which the child (or adult) transcends the culture's normative definitions of male/female to creatively interweave a sense of gender that comes neither totally from the inside (the body, the psyche) nor totally from the outside (the social environment, the culture, others' perceptions of the child's gender) but resides somewhere in between. When converted to a noun, *gender creativity,* the term refers to the act of weaving together nature, nurture, and culture to establish the gender that is unique to each individual, a gender that does not necessarily come in two discrete boxes (the gender binary).

The concept of "gender creative" or "gender creativity" was extrapolated by Ehrensaft from the work of the pediatrician and psychoanalyst, D. W. Winnicott (1896–1971). Winnicott was interested in how people establish their unique individuality. He came up with the concepts of true self (your authentic being), false self (the face you present to the world), and individual creativity (the work you have to do to develop the true self and keep it steady). These constructs seemed a perfect fit when applied to gender development. The true gender self is the authentic core of each of us—in both gender identity (who we are) and gender expressions (how we "do" our gender)—that is male, female, some combination thereof, or neither. The false gender self is the protective covering we develop, either consciously or unconsciously, to keep the true gender self from harm and/or to accommodate to the demands of the external environment. Gender creativity applies to the efforts we make, looking inside ourselves and outside into the world around us. As we do this, we call on both our thoughts and feelings to discover the gender that feels most right for us and one we can comfortably live in. Through these efforts, we strive to make sure the true gender self has room to live and breathe. Said differently, each of us uniquely crafts our gender self on the basis of core feelings about ourselves and our chosen expressions of that self, based in turn on the culture in which we live. This is the essence of gender creativity.

A child governs the weaving of their own gender tapestry; if someone else takes it over, the child's gender creativity is thwarted. If the outer world stomps on their gender creativity, their true gender self is bruised; those individuals will have to make an increased effort at being gender creative in order to keep their true gender self alive. Alternatively, any of those people might collapse under the weight of the stomping, to the point that they may not feel like living at all.

An interesting note about the evolution of *gender creative:* When Ehrensaft was just completing the draft of the book that became *Gender Born, Gender Made,* she presented her ideas for a title to a group of well-established gender specialists, one with a prior career in the publishing industry. She had hoped to title the book *The Gender Creative Child,* but this group of professionals advised against it, as potential readers might misinterpret it to mean that people just created their own gender by volition, rather than discovering it as an authentic core with biological roots. They worried this would do a disservice to the transgender community, particularly in an era of reparative therapy, which was aimed at converting transgender children into cisgender youth with the misguided belief that children's gender identity was malleable and subject to manipulation. Instead, the advice was to introduce the concept within the text, so people would understand its meaning without jumping to misguided conclusions before opening the book. Perceiving these suggestions as wise counsel, Ehrensaft instead came up with the title *Gender Born, Gender Made,* only to discover after publication that the term within the book that appeared most popular was indeed *gender creative*. Soon, the term began to appear widely in conferences, trainings, and writings, as illustrated in the 2012 Gender Creative Kids Workshop held in Montreal, Canada, and then later in the edited volume *Supporting Transgender and Gender-Creative Youth*. Thus, when Ehrensaft wrote her second book on gender-expansive children, she

was now firm in her conviction that the title would be *The Gender Creative Child*.

"Gender creative" has been embraced as a phrase to highlight the part of us that comes up with innovative ways to map out our authentic gender in ways that feel most doable for us in the world we live. It does not signify "make-believe" but rather "make happen." And as a term, it has become widely adopted and has found resonance in other countries, such as Australia, which has its own gender creative history of sistergirls and brotherboys.

In terms of its impact, in 2019, ironically on the 50-year anniversary of the Mattel toy company's introduction of the Barbie doll, Mattel introduced the Creatable World doll, a gender-neutral doll who can fit the profile of the ever-increasing number of children who identify as nonbinary. In Mattel's promotional materials, *gender creative* was adopted as a term to describe their cutting-edge dolls.

The term *gender creative* applies to people of all ages, including parents and caregivers. The gender creative parent or caregiver is one who employs flexibility, self-reflection, and willingness to thinking outside gender boxes to make it possible for their children to follow their own gender creative pathways. In social environments in which gender diversity is not welcomed, a parent's gender creativity will be the most important tool in finding ways for their child's true gender self to be honored while keeping their child protected from harm.

The term *gender creative* also applies to medical doctors, mental health providers, and educators. To become a gender creative professional is to have unlearned gender as one may have been learned it in school, adopting instead a gender affirmative model of care in which gender health is defined as the opportunity to live in one's authentic gender freed from prescriptions, proscriptions, or diagnoses of gender pathology.

Gender Dysphoria

Gender dysphoria describes the discomfort and incongruence experienced when the sex a person is assigned at birth does not match their internal sense of their own gender. Gender dysphoria can be mild or profound, can start in early childhood or later life, and can increase over time. The majority of people who experience gender dysphoria identify as trans, particularly many trans women and men, but also some nonbinary trans individuals. The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*), which was published in 2013, uses the nomenclature of "Gender Dysphoria" to describe the diagnostic criteria necessary to receive medical and surgical treatment. The prescribed treatment involves affirming each person's unique gender identity and expression and providing access to hormonal and surgical procedures.

Defining Gender Dysphoria

The term *gender dysphoria* was coined by Norman Fisk in the 1970s as a way to broaden the parameters of who could or should have access to hormones and gender-affirming surgeries. He conceptualized gender dysphoria as a syndrome and suggested that many people might benefit from medical assistance who did not meet the narrow criteria that had been established by gender clinics in the 1960s. For someone to be eligible for treatment at the time, they needed to be diagnosed as a "true transsexual," which meant that they had a strong, unwavering desire to be the "opposite sex"; hated their genitalia and other physical manifestations of their assigned sex; and were attracted to people of the same sex, but as someone of the

"opposite sex" (i.e., they would be heterosexual after medically transitioning). Mental and physical health care professionals developed an invasive gatekeeping process to control who could have access to hormones and surgeries, arguing that such a system was necessary to avoid treatment regrets. However, many trans people felt that the treatment protocol was rooted in transphobia and a desire to limit trans people's control over their own bodies; they pointed out that other cosmetic surgical procedures (e.g., breast augmentation) did not have any screening process. Trans people and supporters developed trans-affirmative care to challenge the discriminatory gatekeeping system and recognize that the problem of "gender dysphoria" was not with trans people but with a society that did not accept trans people and enable them to be themselves.

Diagnosing Gender Dysphoria

In 2013, "Gender Dysphoria" became a separate diagnostic category in the fifth edition of the *DSM,* replacing the previous nomenclature of "Gender Identity Disorder," which was listed in the section on "Sexual Disorders." The change was made to recognize that gender identity is separate from sexual identity and to lessen the stigma associated with being trans. The new language was intended to send a clear message that a trans person's gender identity is not "disordered" but, rather, that they might experience psychological symptoms because of a mismatch between their sense of self and the sex they were assigned at birth. The *DSM-5* emphatically states that gender-nonconforming expression is not a mental disorder but that the experience of gender dysphoria can lead to clinically significant distress or impairment in various aspects of an individual's life. Discomfort with one's sex assigned at birth may be associated with other identity concerns and may result in other mental health issues, such as depression, anxiety, and eating disorders.

The *DSM-5* describes gender dysphoria in adults and adolescents as marked by an incongruence between one's experienced or expressed gender and one's primary and/or secondary sex characteristics, a strong desire to be rid of one's primary and/or secondary sex characteristics or have the sex characteristics of a gender different from one's assigned gender, to be or be treated as a gender different from one's assigned gender, and/or a strong conviction that one has the typical feelings and reactions of a gender different from one's assigned gender. These experiences must continue for at least 6 months.

The criteria in children include a strong desire to be a gender different from one's assigned gender or an insistence that one is a gender different from one's assigned gender, along with a strong preferences for wearing clothes and playing with toys and games typically associated with a gender different from one's assigned gender; cross-gender roles in make-believe play or fantasy; seeking playmates of a gender different from one's assigned gender; and a strong desire for the physical sex characteristics that match their experienced gender. Additionally, children often voice a strong rejection of toys, games, and activities associated with their assigned gender and a hatred of their genitalia.

The diagnostic criteria for "Gender Dysphoria" in the *DSM-5* recognize the complex ways that people experience and express their gender outside of simplistic male–female/man–woman dichotomies. Definitions have moved away from sexist assumptions about normative social expectations, and the language related to understanding oneself as "the opposite sex" has been replaced with "an alternative gender" to recognize the broad array of gender possibilities, regardless of a person's genitalia. The *DSM-5* also includes recommendations for posttransition treatment, which supports the continuity of medical care—and presumably insurance coverage—after gender dysphoric symptoms have been resolved through medical transition.

Even with the diagnosis being changed from "Gender Identity Disorder," the inclusion of "Gender Dysphoria" in the *DSM* remains controversial because many trans people believe that the mere presence of the category serves to label them as mentally ill. To address this issue, the World Health Organization's newest (10th) edition of the *International Classification of Diseases* (*ICD*) has moved gender-related health issues into a section called "Conditions Related to Sexual Health" and uses the term *gender incongruence,* rather than its previous nomenclature of *gender identity disorder and transsexualism.* These changes will ensure that trans people continue to have access to

trans-affirming health care and insurance coverage while limiting the stigma and discrimination that can accompany mental health diagnoses.

Treatment of Gender Dysphoria

Gender dysphoria often results in anatomical and psychological distress, which can cause complex symptomatology, including anxiety, depression, bodily discomfort, lowered self-esteem, posttraumatic stress disorder, and even suicidality. The level of stress can be especially acute because of gendered sociocultural expectations regarding clothing and hairstyles, occupational requirements, relational and sexual roles, and familial responsibilities.

Trans-Affirming Guidelines

The best "treatment" for gender dysphoria is for trans people to simply accept themselves and express their authentic gender in all aspects of their lives by making changes to their clothing, hairstyle, and other aspects of their gender presentation so that others see them as they see themselves. Trans people can also change their name and/or pronouns to ones that are more aligned with their identity. In addition, various medical interventions can often decrease gender dysphoria. These procedures can include the use of exogenous cross-sex hormone therapy (HT) for adults and adolescents, as well as the use of puberty-blocking hormones for tweens and young teens. Gender-affirming surgeries, such as breast and genital surgery, can also lessen or resolve gender dysphoria.

Although gender dysphoria can be positively addressed through social and medical transitioning, this process can be complicated by many factors, including hostility and rejection from families, partners and friends, workplaces, and the larger society. Trans people's access to medical care can also be hampered by an often transphobic health care system and by not having insurance or having insurance that does not cover trans-affirming care. In addition, some trans people face personal challenges that can make it more difficult for them to come out, including the likelihood of rejection from religious communities, fear of losing custody of children, and having experienced violence, bullying, and abuse in the past for not conforming to gender expectations. Being unable to come out can exacerbate gender dysphoria, as well as psychiatric and trauma-related symptoms.

The goal of treatment for gender dysphoria is the reduction of the distress. Psychotherapy can assist trans people in assessing how they should best move forward and offer support, advocacy, and treatment to assist with the mental health conditions caused by gender dysphoric symptomatology. Developing therapeutic relationships for trans-affirming care can be difficult, because the field has a long history of gatekeeping practices that overevaluated and essentially blocked medical treatment for trans people. This past leads many trans people to distrust mental health care providers, despite advances made in recent years to increase affirmative practices. Psychotherapy is not necessary to receive medical care; many people with gender dysphoria seek hormones and surgeries through the use of medical informed consent procedures. A distinction is made between psychotherapy (a long relational process) and an assessment or evaluation, which can establish gender dysphoria and mental stability and guide the process for a referral to a physician. Most insurance companies require an evaluation for gender-affirming surgery.

It is also important to note that not all trans people experience gender dysphoric symptoms; some do not experience anatomical dissonance or social discomfort in expressing their authentic gender, even if it is at odds with gender expectations. Some gender-nonconforming people are relieved to have their gender identity and expression become congruent; indeed, they describe their experience as one of gender *euphoria*. Trans-related medical treatment should not be determined by the presence of mental health symptomatology but rather should be accessible to all trans people as part of comprehensive trans-affirming health care.

Last, gender dysphoria is not fully resolvable for all trans people, even after they have transitioned. Many continue to struggle with anatomical dissonance, gender incongruence, and dysphoric feelings about their gender expression or identity as a result of still experiencing stigma and discrimination because of being seen by others as trans. For some, there may also be factors that are more psychological and personal.

Standards of Care

The World Professional Association for Transgender Health (WPATH), a multidisciplinary organization that promotes evidence-based care for trans health, has developed gender-affirmative treatment guidelines called the "Standards of Care for the Health of Transsexual, Transgender, and Gender Nonconforming People" (SOC). The SOC are an evolving set of flexible recommendations for practitioners who assess trans adults for hormone treatments and gender-affirming surgeries. Mental health providers, including social workers, mental health and professional counselors, marriage and family therapists, psychologists, and psychiatrists who are trained in working with trans people, are eligible to assess clients for gender dysphoria, recommend treatment, and make a referral for medical care.

The SOC state that gender-nonconforming behavior is an aspect of human diversity and not a form of pathology. The guidelines also recognize that a diagnosis of gender dysphoria should never be used to further stigmatize trans people. While such a diagnosis can sometimes increase minority stress, it can also facilitate access to treatment.

Gender Expression

Gender expression is a mutable social portrayal of one's self. For trans people, such a tool for self-portrayal can be critical to self-actualization and social communication. Important to understanding gender expression as it pertains to transness are its material manifestations, social contexts, and implications for wellness.

Expression can refer to any way an individual occupies and adorns their own body and relates to other bodies. Below is an inexhaustive list of tools people often use to express gender:

Hair (style, length, color)

Labels (names and pronouns)

Clothes (cut, colors, patterns)

Social actions, interactions (sharing emotions, touching, facial expressions)

Jewelry (piercings, metals, cuts)

Roles and labor (career choices, family and relationship roles)

Makeup (face and body makeup, nail polish color, feature accentuation)

Activities, hobbies (sports, games, personal interests)

Speaking (cadence, voice inflection, volume, tone)

Smells (odor strength, origins, inspirations)

Gender expression is constitutive of social markers a person places on their body (clothes,

jewelry, makeup, scent) and social markers they use to relate to others (speaking style, body language, types of labor). Depending on the culture and environment, these markers are coded as masculine, feminine, neither, or both. In the modern United States, markers often coded as feminine are dresses, colorful makeup, and expressive speaking styles. Those often coded as masculine are knee-length shorts, affinity for sports, and a blunt manner of speaking. Notably, there are countless markers that are not often gendered as masculine or feminine or are most often gendered according to context; some examples of this are crewcut T-shirts, concealer, ponytails, jeans, sneakers, careers in retail, and interest in education. Marker gendering is a subjective practice and often very personal; all gendered markers are subject to contextual interpretation. Beyond binary terms, manifestations of these markers in concert with one another create a composite image of one's gender expression at any given moment.

Gender Expression as Distinct From Gender Identity

Gender *identity* is the way one conceptualizes and labels one's own sense of self. Gender *expression* is an (often circumstantial) social manifestation of one's gender. Gender expression and identity are related insofar as there are cultural associations and expectations for certain identities and expressions (e.g., the expectation that someone identifying as a man would express their gender in a masculine way). However, there are no unprecedented combinations of gender identity and expression. One can be a transgender man without taking any measures to socially or medically transition, wear dresses and makeup, and still consider oneself a man, likewise for a cisgender man who wears dresses and makeup and does not consider themselves transgender in any way. A lack of concordance between gender expression and identity is not incorrect, nor is it necessarily temporary; gender expression can be a small piece of how an individual conveys their gender identity.

For many people, both trans and cis, it is important to have social "concordance" between gender identity and expression. A disparity between the two can cause significant distress. For trans people, this distress is often referred to as *gender dysphoria*. Gender dysphoria can be a source of serious health consequences for trans people and is sometimes characterized by a sense of discordance between identity and expression.

Gender Expression as Distinct From Gender Performance and Gender Performativity

Expression is not strictly distinct from performance. It would be precedented to say that expression is body centered and performance is behavior centered. It would also be precedented to contend that both terms involve both body and behavior.

Gender performance and *gender performativity* as terms can reference the notion that gender is not innate but iteratively performed and belabored and that our expectations for a gendered existence are constitutive of our ongoing occupancy of those behavioral enclaves from which we seldom deviate. This means that prior to entering a social space, our roles, labor, and conduct are socially preordained. *Gender expression* as a term references gender markers themselves rather than the notions of gender as learned or innate.

Gender Expression as Contextual

Gender expression can be contextualized by race, socioeconomic position, and culture. Because gendered meanings have cultural histories, an aspect of expression that can be gendered a certain way by one culture may have a different meaning in another culture. Because of the subjectivity of gender expression, it would be impossible to fully understand the term's depth and breadth without exploring the way it interacts with other identities, circumstances, and contexts.

National Origin

A common example of a nationally specific gender marker is the Scottish kilt. In Scotland, the kilt is a gender marker consistent with notions of masculinity. However, to people socialized in the United States, the garment looks like a skirt and is often coded as feminine. Often, men wearing kilts are seen by Scottish people as masculine and by American people as feminine.

Region and Class

Interpretations of gender markers can also vary by localities and class; socioeconomic groups can create gender meanings specific to their cultural context. For example, a rural community whose local economy is driven by agriculture may be characterized by a gendered labor division different from that of nearby urban communities. In this example, it may be seen as masculine for someone to hold a desk job in an urban setting but less so in a rural setting, where the means of production are driven by manual labor and where desk labor is considered a less masculine alternative.

Race

To exist in a racialized body will affect the way one's gender is articulated and socially received. In the context of an American sociocultural ethos, an American queer Black man expressing femininity through dance (e.g., voguing) may be articulated in the context of the rich cultural history of the house-ballroom community. It also may be articulated in the context of expressing one's diasporic identity. Such a femininity inevitably operates at odds with the expectation for hypermasculinity that whiteness created for Black American men (and non-Black men of color). Queer femininity on a white body may have similar cultural influences by virtue of an adjacent queer history but, articulated through a white body, will neither be performed nor read in the same way.

Sexual Identity

There are countless gender identities and expressions stemming from queer subcultures that reference gender specificity among sexual minorities (e.g., butch, femme). Gender expression can be a highly meaningful and visible signifier for sexual minorities. An example of gender expression signaling sexual identity can be recognized in "female" masculinities within queer American subcultures. Masculinity that is articulated by a woman identifying as "butch" is distinct from masculinity articulated by a binary man, even though the markers may be exactly the same. In other words, a suit and tie on a butch woman is not always the same gender expression as a suit and tie on a cisgender man; the difference lies in their different gender identities and how their masculinity is perceived and interpreted by others within their subcultural context.

Any culture's frame of reference for gendering markers is subject to change over time. As style and culture shift, our understanding of gender changes—as does our conception of certain markers as masculine or feminine. An example is the high heel: While in many modern cultures, high heels are seen as feminine, in the 15th century, high heels were associated with masculine aristocracy and even martial prowess. It was in the 1600s that feminist women of the time co-opted the "elevated heel" to assert equality to men and "masculinize" their dress. When reading the gender presentation of someone from a past era, they must be viewed through a lens of gender standards of the time and culture.

Gender Expression as Intentional and Unintentional

Gender expression is "expressed" whether known or unknown to the subject. What may deviate from body to body is the importance of articulating one's gender in a specific way. That is, even those who default to social concordance between their assigned sex, identity, and gender expression without thinking about gender *are* expressing their gender. The extent that gender expression is important to an individual's identity will vary from person to person.

Limitations of the Feminine–Masculine Descriptive Dichotomy

Because gender expression is a product of many social markers, expressing nonbinary gender can be conceptualized as a mixture of markers socially coded as masculine and feminine. However, those who identify with a nonbinary gender may not conceptualize their gender expression as "masculine," "feminine," or on any two-dimensional continuum involving masculinity and femininity as the extremes. The masculine–feminine bipole obscures the multidimensionality of gender expression and identity and thus can be conceptually limiting.

Public Safety: Perception of Assigned Sex, Gender Identity, and Gender Expression

There are major safety implications for expressing gender that are not socially concordant with one's perceived assigned sex at birth. The 2015 United States Transgender Survey (USTS) (N = 27,715) found that a substantial percentage of respondents "who were out or perceived as transgender" while in school were verbally (54%) or physically attacked (24%) and/or sexually assaulted (13%). The mistreatment incurred at school caused 17% of respondents to leave school. Discrimination in public spaces outside school were similarly pervasive, with 46% reporting verbal harassment, 9% reporting physical abuse, and 10% reporting sexual assault *just in the one year* prior to survey completion.

Such vulnerability to violence is compounded when race renders an individual more visible as a target for harassment or discrimination. The USTS found that 19% of American Indian[1] trans women had been physically attacked by strangers in public in the past year, compared to 6% of white trans women. Furthermore, 11% of Black trans women had been attacked with a gun in the past year, compared to 3% of white trans women.

Due to anti-trans prejudice, identifying and expressing a gender at odds with one's perceived assigned sex is enough to render someone vulnerable to potentially lethal prejudicial violence. The role of gender expression is rendered even clearer when statistics indicate that trans people are being attacked *by strangers* who may be unaware of the person's gender identity; this suggests that the way trans people are being socially read by those in their surroundings is central to their vulnerability to violence, as opposed to their personal identities.

Seeking Safety: Withholding an Authentic Gender Expression

Since expression of gender for trans people can have such dangerous implications, public gender expression is often contingent on perceived safety. If a trans woman does not feel like she can "pass as a woman" in a particular social setting and fears the consequences of being read as a man expressing femininity, she may opt to express her gender according to what may render her the safest rather than what is most concordant with her identity. In fact, the USTS found that 43% of nonbinary respondents opted not to disclose their nonbinary identity to others because they "might face violence." This expectation for violence has a profound impact on willingness to express gender authentically.

The external social influences associated with gender expression have health implications for trans people beyond the acute susceptibility to violence. When trans people need to express an inauthentic gender for safety and are misgendered as a consequence, this can be heavily taxing on one's mental (and overall) health. According to the USTS, 40% of trans people have attempted suicide in their lifetime (compared with a rate of 4.6% for the general population). Such a staggering health disparity is illustrative of the historically inhospitable social ethos for authentic gender expression among gender-diverse people.

Conclusion

Gender expression comprises how people articulate their many identities, is limited by one's sense of safety and means to express oneself, and is received by a subjective audience. For trans people, authentic gender expression is central to safety and self-actualization and can be a source of vulnerability to prejudicial violence. Importantly, authentic gender expression is also a key mode of communicating a sense of self to one's surroundings and a can be a source of joy for trans people who can do so freely.

[1]The term "American Indian" was the term used for USTS data collection to enable comparisons with US governmental surveys, and therefore describes how respondents self-identified in that survey. Indigenous people living in the lands currently known as the United States may use a broad range of terms to describe their identity.

Gender Fluidity

Gender fluidity refers to a gender expression or gender identity that is fluctuating (i.e., changes over time). The term *gender fluid* can be used as an adjective that describes expression in the context of a different gender identity ("I am a gender-fluid man") or as a standalone identity term ("I am gender fluid"). To understand gender fluidity, it is important to think about how it relates to expression and identity, as well as the relationship between gender mutability and legitimacy. Critical to ascertaining the meanings behind a fluctuating gender identity and expression is understanding institutional barriers that give meaning to this iteration of gender difference. The following sections discuss the nature of gender fluidity as experienced within a sociocultural context of gender binarism.

Expression, Identity, and Binarism

Expression

Gender expression is a term that references an individual's self-portrayal, which often consists of clothes, makeup, affect, and other innumerable markers of gender. A gender-fluid expression is one that changes as a function of time, context, or otherwise; an individual with a fluid gender expression may express their gender in a way that is typically read as masculine on some days and more feminine on other days.

The moving pieces for gender-fluid expression are not always masculinity and femininity, as not every gender-fluid person uses these terms as cardinal directions to orient their gender expression. Someone who is gender fluid, who does not use masculinity or femininity as a metric for their gender expression, may just wear what makes them feel comfortable on any given day without thinking through a masculine–feminine gender lens. For example, a trans girl who describes her gender expression as fluid may wear makeup, a septum piercing, and sweatpants on one day and wear no makeup, don braided hair, and a sundress on another day but not think of either as distinctly masculine or feminine.

Gender expression, fluid or otherwise, is subject to contextual interpretation. One can embody a fluid gender expression and hold any gender identity. For example, a person may have a consistent gender identity (e.g., agender), and their gender expression varies between masculine and feminine depending on the day or occasion. Moreover, a person's race, nationality, class, religion, or other social identity or experience influences and adds meaning to their gender expression. For example, a person with a gender fluid expression who lives in the Iranian diaspora navigates both their Iranian as well as their new home country's gender norms. In this case, gender expression is mediated through race, nationality, and diasporic identity.

Identity

Gender identity is a term that references a person's own sense of gender. Gender fluid can describe an identity and is often used to capture the dynamic nature of one's gendered self-concept. Someone who identifies as gender fluid may align themselves with certain gender(s) for some period of time and align themselves with other gender(s) at other times—all of these gender identifications comprise gender fluidity as opposed to a linear, stepwise model of gender identity development that both assumes and results in a stable, nonfluid gender identity. Consider an example in which a person began identifying as gender fluid in 2014,

spent the year 2015 expressing as a binary man and the next 2 years as a binary woman, and then expressed themselves as nonbinary throughout 2018. While their gender expression and pronouns changed accordingly through the different years, they continually identified as gender fluid.

Binarism

Gender fluidity can be constitutive of binary and/or nonbinary gender expressions and identities. By virtue of its variability, gender fluid–identified people generally do not identify as or express one binary gender. In this way, gender fluid as an identity or expression relates to the terms *trans* and *nonbinary*. While some gender-fluid people may use trans and/or nonbinary as accurate descriptors, they may not claim them as identities. Furthermore, gender-fluid people may identify as trans and/or nonbinary, but not all trans and nonbinary people are gender fluid; thus, the terms cannot be used interchangeably.

Contextualized by Other Identities

Gender fluidity is externalized by a nuanced actor, received by a subjective audience, and situated in any given sociocultural context; that is to say, to have a national, racial, or cultural identity will interact with gender fluidity in important and distinct ways.

Race, Faith, and Diaspora

Consider an adolescent assigned female at birth who identifies as gender fluid, uses they/them pronouns, lives in first-generation Iranian diaspora, and practices Islam in the United States. As a part of their practice of Islam, they sometimes wear a hijab (head covering), which is typically worn by individuals assigned female at birth. For this adolescent, wearing the hijab started as an expression of modesty and developed in the diaspora into an expression of their faith. Because they live outside of Iran, which is governed by a theocracy, their thoughts about wearing the hijab voluntarily in diaspora are often influenced by the fact that many people living in Iran are legally obligated to wear head coverings. Furthermore, in the United States, it is possible that their school and family environment are culturally different enough that multiple measures must be taken to communicate an authentic gender at any given moment. For example, the importance of wearing a hijab may be different at school if their religion may not otherwise be clearly communicated in a Muslim-minority setting. Externalizing this piece of gender expression, the hijab, is affected by environment, and its meaning is developed over time. The fluidity of this person's gender thus is simultaneously shaped by cultural precedent, Islamic faith, Iranian identity, diasporic identity, and gender authenticity.

Urbanicity and Sexuality

Consider a pansexual gender-fluid person (she/they) who was assigned male at birth and grew up in a rural area. When in her small hometown, she might affirm her gender by painting a few fingernails and donning colorful and patterned shirts and pants. They also dress feminine more often than masculine to emphasize their non-cisgender, as well as pansexual, identities. In this context, attire signals gender fluidity at home where there are fewer visibly queer people. When in a more urban space and surrounded by more gender-nonconforming people, there are different pressures that require negotiating her relatively unique cultural ethos with the urbanicity of her trans peers. She does not feel the same pressure to emphasize femininity, because nonphysical gender markers are legible enough; she feels seen and understood in her gender-fluid identity regardless of her clothes and accessories. She is less often assumed to be cis and heterosexual by her urban community of queer people.

Gender Fluidity and Legitimacy

Gender fluidity, as an expression or identity, is rooted in its being subject to change. Fluid gender may be a function of change in any increment of time (seconds, minutes, hours, days, weeks, months, years, etc.), and it need not be monochronic (one gender expression and identity at a time) or along regular time intervals. For example, a gender-fluid person (expression and identity) might spend 1 month dressing as masculine, then for a few days wear dresses and makeup, and then dress in a masculine way for 2 weeks until expressing themselves in feminine ways, and so on. Despite a changing expression in their dress, they always use they/them/their pronouns. Another example includes a

gender-fluid woman (expression) who dresses in jeans and a T-shirt but will also wear a tuxedo on special occasions. In a final example, a gender-fluid person (identity) may have an outward gender expression that rarely changes but an inner sense of self that changes from day to day in the form of pronouns. Ultimately, there are innumerable variations of gender fluidity in the realm of identity and expression. The driving force of gender fluctuation is always the individual's sense of self, based on what feels right. "What feels right" is the fluid aspect of gender.

It is important to acknowledge gender-fluid people's identities through the correct use of gendered terms, name(s), and pronoun(s). By virtue of holding an expression or identity that is by nature dynamic, a person who is gender fluid may have different names and pronouns at different times, which may prompt the need to ask about name, pronouns, and other terms more than once.

Legitimacy

Nonnormative gender expression can render any person (regardless of identity) vulnerable to prejudicial violence and discrimination. Authentic gender expression for gender-fluid people may be influenced by perceived safety and social comfort. To the extent that gender-fluid people feel safe doing so, change in their self-manifestation is a function of what a gender-fluid person feels is authentic in any given moment.

Access to interventions for gender actualization—such as legal name changes, changes to identification documentation, or medical transition services—requires one's gender expression and identity to be endorsed by gatekeepers. Two major arbiters of gender legitimacy are the institutions of law and medicine. However, the predominant framework that informs medical and legal infrastructure regarding sex and gender is based on cisgender notions and, therefore, makes three assumptions: Gender is a binary, gender is immutable, and gender identity originates in early childhood. Such assumptions enable the legitimacy of binary trans people who have known about their gender since early childhood, albeit through gatekeeping. Such legitimacy functions to exclude nonbinary-identified trans people and trans people with gender-fluid identities.

The lack of legitimacy afforded to gender fluidity can be observed in psychological and state exclusions. The American Psychiatric Association's diagnostic criteria rely on time-based expression of symptoms, and most individual U.S. states require either/or gender classification. The underlying assumption in existing medical and legal infrastructure is that a gender transition has *one destination;* administrative space for gender mutability is still lacking.

In conclusion, gender fluid refers to a dynamic descriptor of expression and identity and applies to many ways of embodied existence. Crucial to the acknowledgment of and accommodation for gender fluidity is creating cultural and legislative space for the ways that gender manifestations shift across time and contexts—social, geographic, or otherwise.

Gender Functions

Gender is often conceptualized as a descriptive category comprising various components (e.g., identity, expression). However, gender(s) also fulfill a number of important personal, political, and social functions. Considering the *functions of gender* allows researchers and theorists to explore the reasons why unique genders evolve, the needs that they fulfill within communities, and the way they function interpersonally. An understanding of the purpose and functions of gender may render gender diversity more intelligible and less threatening to those who find it so. This entry first reviews key concepts related to gender and finishes by summarizing concepts from the humanities and social sciences that describe the various functions that gender can play, with a particular emphasis on the function of genders developed within various subcultures of the broader lesbian, gay, bisexual, transgender, queer, intersex, and asexual (LGBTQIA+) community (e.g., LGBTQIA+ genders).

Review of Key Terms

Components of Gender

Often when people talk about gender, they are referring to the constellations of traits that social groups conceptualize as indicative of specific gender. However, gender comprises several intra- and interpersonal constituent components. For instance, *gender identity* captures an individual's internal felt sense of their gender, while *gender expression* refers to how someone expresses, presents, or otherwise performs their gender. Gender is expressed through various visual and behavioral cues such as clothing, haircut, accessories, mannerisms, and vocal patterns, among others. Aspects of gender expression are independent of gender identity; someone who identifies as a woman may express their gender with physical or personality traits that historically have been labeled as "masculine," as in the case with butch lesbians, for instance. Aspects of gender are also not synonymous with sex assigned at birth, which is based mostly on external genitalia but also includes chromosomal, hormonal, and other physical characteristics that become apparent across the life span.

Binary Conceptions of Gender

Within mainstream U.S. society, the dominant conceptualization of gender typically is restricted to traits associated with either men or women who are assumed to be heterosexual and cisgender. The medical and social sciences have tended to define gender as culturally grouped traits that are associated with being female or male. Such traits include behaviors, attitudes, feelings, relational styles, and general personality and interests that are socially labeled as masculine or feminine. This naturalistic perspective presumes both a sexual and a gender binary in which each category is mutually exclusive (i.e., male–female, man–woman) and therefore tends to conflate sex with gender (i.e., males are assumed to be masculine men, females are assumed to be feminine women). These genders, men and women, are thought to conform to socially prescribed *gender roles,* which are external scripts that presume individual traits and interpersonal dynamic patterns based on a person's masculinity or femininity and tend to position masculinity and femininity in opposition to each other (e.g., one is *either* a man or a woman). However, this narrow definition may erase diverse gender experiences. Indeed, attempts to articulate LGBTQIA+ experiences in mainstream professional settings (e.g., academic writing, medical texts, legal policies) are typically rooted in binary concepts of sex and gender; for example, stating that homosexual people are attracted to the "same sex" or a trans person's experienced gender is the "opposite" of their sex assigned at birth oversimplifies these experiences and reifies binary definitions of sex and gender.

Gender Performativity

Despite the fact that these restrictive concepts of gender remain dominant in mainstream discussions of such topics, many have critiqued these socially prescribed genders. Feminist scholars through the latter half of the 20th century highlighted the inextricable influence of social forces on conceptions of gender, arguing that gender is a social construct and that one becomes, rather than is born into, their gender. Queer and gender theorists from the 1970s onward, building on postmodernist philosophical concepts from the former half of the 20th century, took a social constructivist approach to understanding gender and to

critique essentialist views of gender. These theories emphasize the oppressive roles of dominant heterosexist and patriarchal values in shaping conceptualizations of gender, such that heterosexuality is presumed to be the norm and therefore people are assumed to have attraction solely to people of the "opposite" sex or gender.

A core concept in queer theory is the idea of gender performativity, which states that queer gender identities represent a subversive repetition of gender performances. In Judith Butler's 1990 influential work, *Gender Trouble,* she describes gender as a set of repetitive characteristics and performances that become organized into different socially transmitted conceptions of gender. Because the same associations between sets of characteristics and genders are reinforced repeatedly in popular media and interpersonal relationships, they become socially expected. This approach to understanding gender has been helpful in conceptualizing how people learn about masculinity and femininity. It provided a persuasive explanation for how genders become naturalized and come to be seen as normatively linked to sex. However, it did not seek to explain the evolution of new LGBTQIA+ genders and why and how they function.

LGBTQIA+ Genders

Because assumptions about gender binarism are embedded in so many social discourses and practices, LGBTQIA+ people often are positioned as needing to resist an overwhelming and encompassing gender hegemony. LGBTQIA+ individuals have developed a variety of unique and longstanding gender expressions and identities such as *trans, butch, femme, bear, leatherman, masculine of center,* and more in response to heteronormative gender roles and restrictive conceptions of gender. These unique identities can be conceptualized as LGBTQIA+ genders because they originated within these marginalized communities to formalize and describe the experiences of gender within them. LGBTQIA+ genders allow sexual and gender minority individuals to articulate their sense of self and can bring together people who share commonalities and assist them in arguing for rights and fair treatment. Rather than viewing these genders as defining restrictive gender roles, LGBTQIA+ genders can be considered in terms of the personal and social functions of embodying a gender that is rooted in people's authentic sense of themselves.

Functions of (LGBTQIA+) Gender

Since the new millennium, scholarship has increasingly conceptualized varied genders as developing in relation to dynamic psychological, historical, and social processes. At the same time, there has been an increased public discourse about gender and sexual orientation as being essential or biologically based experiences. LGBTQIA+ genders often have been central in these debates because of the proliferation of gender identities and cultures (e.g., trans, boi, gender nonconforming, nonbinary). Social science and humanities research from the early 2000s onward, summarized in more detail in Heidi Levitt's 2019 article, "A Psychosocial Genealogy of LGBTQ+ Gender," has articulated how gender can function in the lives of people with varied LGBTQIA+ gender identities. The functions of LGBTQIA+ gender across four key domains are described in what follows and illustrated with examples from particular subcultures, emphasizing examples from trans populations.

Psychological Functions of Gender

Claiming and embodying an LGBTQIA+ gender permits a sense of authenticity in relation to people's core internal sense of self. Many LGBTQIA+ people receive messages during critical developmental periods (e.g., childhood, adolescence) that devalue their gender or leave them feeling rejected and alienated if they do not have the language to explain their sense of difference or advocate for themselves. Finding a gender identity that is congruent with someone's internal sense of gender can allow them to make sense of their selves, strengthen their sense of identity, and signal personal values and position people in relation to others. For instance, in the case of trans women who experience erasure in the LGBTQIA+ community, the sense of solidarity in identifying as trans may facilitate a sense of belonging to the broader LGBTQIA+ community. The gender that feels most authentic may evolve as new gender identities are learned about and become viable. For instance, some trans men may first identify as butch lesbians before their gender identity evolves.

Psychologically, the advantage of adopting an LGBTQIA+ gender identity may be the development of an authentic sense of self, language that can be used to advocate for oneself, and sense of connection with others who have a similar gender experience.

Cultural Functions of Gender

LGBTQIA+ gender identities and communities have developed as a response to oppressive social norms that restricted the claiming and enactment of gender, denigrating people who deviated from dominant cultural archetypes that could occur within heterosexual or LGBTQIA+ contexts. For instance, butch and femme lesbian identities evolved in the 1940s to 1950s as a response to the expectation that all women would conform to singular gender expressions. Leathermen as a community countered the idea that all gay men would be effeminate. Trans cultures emerged to resist the gender binary system and put forward alternatives. In each case, LGBTQIA+ gender cultures functioned to reconcile or reclaim needs and desires that were denied by mainstream culture (e.g., you cannot be female and masculine or gay and masculine), undercutting their needs for personal integrity, authenticity, and a sense of belonging. These cultures allow individuals to embrace marginalized or seemingly discordant aspects of themselves, with a sense of pride. For example, house-ballroom communities offer a refuge for racial, ethnic, gender, and sexual minorities to not only resist heterosexism, cisgenderism, and sexism but also the racism, ethnocentrism, and classism that are not always acknowledged in the broader LGBTQIA+ community. Whether in the affiliative context of gender communities or not, LGBTQIA+ gender identity cultures allow people to challenge and redefine rigid social constructs about gender and to counter prior stigmatizing discourses.

Interpersonal Functions of Gender

As LGBTQIA+ gender cultures form, symbols of those cultures come to signal the acts of resistance that are at the heart of each culture. For instance, some people may choose to show signs of their community (e.g., butch star tattoos, bear flag), piercings, or hairstyles to signal affiliation with an LGBTQIA+ gender community. Still others may emphasize certain aspects of their gender expression to communicate important parts of their identity or critique assumptions about gender, as in the case of drag performers who use deliberately ambiguous or exaggerated signifiers of gender. These signs of LGBTQIA+ genders can confer status and belonging upon the wearer, a function of gender that can be deeply appreciated after years of feeling marginalized. These signifiers can allow for welcomed recognition by others in the same community, but they also can increase the risk of heterosexist and transphobia incidents. As a result, people may deliberately minimize these indicators when sensing that being seen as LGBTQIA+ might place them at risk (e.g., by butching up, acting demure, going stealth). Still, some LGBTQIA+ people do not want to pass as cisgender or heterosexual, and any efforts may come too late or be unsuccessful. Dire consequences of being visibly LGBTQIA+ have been documented by findings that gender nonconformity places one at greater risk of discriminatory treatment and violence. Still, this interpersonal sense of connection, belonging, and status is such a powerful function of gender that it often motivates community members to adopt gender signs.

Sexual Functions of Gender

As LGBTQIA+ gender signifiers develop within a community, they come to convey aesthetic values of that gender. Behaviors, appearances, relational dynamics, and identities that historically were viewed as shameful or wrong became prized and eroticized—in stark opposition to oppressive social contexts. The aesthetics often subvert assumptions about sex and gender by embodying the form of subversive resistance that had drawn the community together. For instance, a genderqueer community might eroticize androgynous aesthetics, and butch masculinity might be idealized and seen as highly attractive. Rendering diverse LGBTQIA+ genders as sexually desirable functioned to increase individuals' sexual self-esteem as it replaced messages of shame with those of pride. They presented an alternative to the dominant mainstream images of attractiveness—that is, white, cisgender, heterosexual, able-bodied, thin—as well as the dominant images in mainstream LGBTQIA+ cultures. New

forms of gender, such as those developed in balls and pageant performances, may be erotically affirmed. LGBTQIA+ gender identities also support people to engage with each other sexually while being authentic to themselves. They allow partners to understand what sexual acts might be affirming or invalidating, and they facilitate acceptance and pride. This approach to gender theory highlights the ways in which gender evolves and functions within trans communities and is based upon the lived experiences reported by LGBTQIA+ people in diverse gender communities. It demonstrates the connection between gender and sexuality and documents the relevance of trans gender identities across central domains of human experience.

Gender Identity Discrimination as Sex Discrimination

Almost from the moment the earliest legal protections against sex discrimination were enacted, individuals have advanced the theory that discrimination based on gender identity or trans status constitutes a form of sex discrimination. In the United States, such arguments initially were often met with resistance from courts interpreting sex discrimination laws. Beginning in the early 2000s, however, courts increasingly began to accept this idea, applying various rationales to conclude that discrimination against a person based on their gender identity is prohibited under laws or policies that protect individuals against sex discrimination. In 2020, the U.S. Supreme Court accepted this theory, ruling that trans employees throughout the country are protected from discrimination based on gender identity under Title VII of the Civil Rights Act of 1964, a federal law that prohibits discrimination in employment because of sex.

Early Sex Discrimination Arguments

Almost immediately after the 1964 passage of the Civil Rights Act, debate began about the meaning, breadth, and application of its sex discrimination provision. For example, the Equal Employment Opportunity Commission, the federal agency charged with its enforcement, initially concluded that listing men's and women's positions separately in job postings did not violate Title VII, only to reverse that stance by the end of the 1960s.

Trans employees who lost their jobs also began to see that the breadth of Title VII's sex discrimination provision might mean the law protected employees who were fired because of their gender identity or transition. These claims were generally met with resistance by federal courts, which often rejected them with little analysis. In a 1977 case that was typical of these early decisions, an employee of an accounting firm began receiving hormone therapy, changed her name, started planning for gender-affirming surgery, and took other steps to transition. When the employer terminated her, she filed a lawsuit under Title VII. A federal court of appeals rejected her claim, concluding that in enacting Title VII, "Congress had only the traditional notions of 'sex' in mind" and that these traditional notions did not encompass gender transition (*Holloway v. Arthur Anderson & Co.*, 1977). One member of the three-judge panel dissented. He stated that the plaintiff did have a claim under the statute because she was allegedly fired for indicating to her employer that she was female

and seemingly would not have lost her job had she continued to be perceived as male.

Although at least some believed from the outset that sex discrimination included gender identity discrimination, those views did not prevail initially. They began to achieve wider acceptance only after further developments in other areas of sex discrimination law made clear that Title VII prohibits more than terminating women because of their sex or adopting workplace rules that treat women less favorably than men.

The Early 2000s: Emerging Consensus That Sex Discrimination Includes Gender Identity Discrimination

Although *Holloway* and similar cases reflected the prevailing view for the next 25 years, later developments in the Supreme Court's sex discrimination jurisprudence made the position that Title VII does not protect trans people appear increasingly untenable. The Court held, for example, that rules treating individual men and women differently in the workplace could not be justified by arguing that the purpose or effect of the rule was beneficial to women as a group or that the rule was based on "real" differences between the sexes such as in life expectancy. Title VII was concerned with an employer's treatment of individuals; whether that individual employee was typical of women or men as a class was irrelevant.

Most significant for purposes of gender identity discrimination was the Supreme Court's 1986 decision in *Price Waterhouse v. Hopkins*. In that case, the Court determined that a female employee who was denied a promotion because she was described as "macho" and did not walk, talk, or dress "femininely" or wear makeup and jewelry could state a claim for sex discrimination under Title VII, even though she was not discriminated against simply for being a woman rather than a man.

Price Waterhouse made clear that sex discrimination includes not merely discriminating against men or women as groups but also discriminating against individuals because they do not conform to an employer's gender-based stereotypes about how employees should dress or act, even if Congress did not have that result in mind in 1964. That conclusion was underscored by a 1998 decision in which the Supreme Court concluded a male employee who alleged that he was singled out by his male coworkers for sexual harassment could bring a claim for sex discrimination under Title VII. The Court stated that it was irrelevant that addressing male-on-male sexual harassment was not the aim of Congress in enacting Title VII, as it is "the provisions of our laws rather than the principal concerns of our legislators by which we are governed" (*Oncale v. Sundowner Offshore Services, Inc.,* 1998).

These developments in sex discrimination doctrine opened the door to renewed consideration of the impact of Title VII on trans workers. If Title VII prohibited Price Waterhouse from discriminating against Ann Hopkins because she was perceived as a woman who was too masculine, why would it not also prohibit discrimination against trans employees who did not conform to an employer's stereotypes about how women or men should look or behave?

In 2004, the U.S. Court of Appeals for the Sixth Circuit became the first federal court of appeals to conclude that Title VII prohibits discrimination against trans employees. The court ruled that a city fire department employee in Ohio who was in the process of transitioning and faced workplace discrimination for having a more traditionally feminine appearance and manner could assert a claim under Title VII, because the discrimination would not have transpired if not for the employee's sex. The court observed that "discrimination against a plaintiff who is transsexual—and therefore fails to act and/or identify with his or her gender [assigned at birth]—is no different from the discrimination directed against Ann Hopkins in Price Waterhouse, who, in sex-stereotypical terms, did not act like a woman" (*Smith v. City of Salem,* 2004).

By 2020, 5 of the 12 federal courts of appeals had considered similar cases and concluded that disparate treatment of trans individuals constituted impermissible sex discrimination under federal antidiscrimination statutes. None had set a precedent to the contrary, and at least two had overruled earlier decisions stating that sex discrimination did not include gender identity discrimination.

2020: The Supreme Court Rules That Sex Discrimination Includes Gender Identity Discrimination

On June 15, 2020, the U.S. Supreme Court settled the sex discrimination question for purposes of

federal law, ruling that Title VII protects employees against discrimination based on their gender identity or trans status. The decision in *Bostock v. Clayton County* (2020) addressed three cases, including that of Aimee Stephens, a trans woman who was terminated from her job as a funeral director in Michigan when her employer learned that she was trans. The Supreme Court ruled that Stephens was entitled to bring a Title VII claim against her employer because terminating an employee at least in part because of the employee's trans status constitutes sex discrimination under federal law. In the same decision, the Court also considered the claims of two gay men who were fired after their employers learned they were gay, ruling that firing an employee because of their sexual orientation also constitutes sex discrimination under Title VII.

The Supreme Court decided the case on a 6–3 vote, with Justice Neil Gorsuch writing for the Court's majority. Justice Gorsuch's majority opinion held that "an employer who fires an individual for being homosexual or transgender fires that person for traits or actions it would not have questioned in members of a different sex. Sex plays a necessary and undisguisable role in the decision, exactly what Title VII forbids" (*Bostock v. Clayton County,* 2020).

The Court began its analysis by stating that Title VII must be interpreted according to the "ordinary public meaning" of its terms at the time of its enactment—that is, the way the words used in the text would have been understood in 1964, not necessarily what Congress intended to do or the way courts expected particular cases to be resolved at that time. Applying this mode of interpretation to Title VII's prohibition on sex discrimination, the Court reasoned that an employer who treats an employee less favorably because of sex, such as by firing the person for conduct or traits it permits for employees of another sex, violates the law.

With respect to discrimination based on gender identity or sexual orientation specifically, the Court concluded that "it is impossible to discriminate against a person for being homosexual or transgender without discriminating against that individual based on sex." To illustrate the point with respect to trans employees, Justice Gorsuch pointed to the example of an employer who fires a trans person who was assigned male at birth but identifies as a woman; if the employer retains otherwise identical women employees who were assigned female at birth, the employer discriminates based on sex because it penalizes an employee identified as male at birth for characteristics or actions that it permits in an employee identified as female at birth.

The Court also observed that it was irrelevant whether an employer refuses to employ both trans men and trans women, rather than discriminating against only trans men or only trans women. This was because Title VII prohibits each instance of discrimination against an individual employee because of that individual's sex, regardless of whether such treatment favors men or women as a class overall.

The decision in *Bostock* clearly established that firing a trans employee based on their gender identity or transition constitutes sex discrimination under Title VII. It also likely means similar results will apply for purposes of federal and state laws prohibiting sex discrimination in education, housing, and other areas. Much remains to be resolved, however, about the application of *Bostock* to other specific forms of discrimination, such as denials of insurance coverage for transition-related care, access to sex-separated restrooms and locker rooms based on gender identity, and other forms of discrimination that do not involve refusal to hire or termination of employment.

Gender Labels

Gender is a multidimensional construct that is inclusive of *assigned gender/sex, gender identity, gender expression,* and *gender roles/expectations.* Gender labels may refer to a single dimension of gender or may be used to refer to gender as a broad overarching concept. Gender labels can also specifically reference the relation between one dimension (e.g., assigned gender/sex) and another (e.g., gender identity). For example, *cisgender* or *cis* is a gender label used to refer to individuals whose gender identity is coincident with their assigned gender/sex, while *trans* is used as a label for individuals whose gender identity and assigned sex do not correspond. It is important to note that these different dimensions of gender are not always "aligned" with one another, nor should they be expected to be aligned. That is, two people with the same assigned gender/sex (e.g., female) may differ in gender presentation (e.g., androgynous, feminine, masculine) and gender identity (e.g., agender, genderqueer, man, nonbinary, woman). Alignment normativity is the assumption that alignment between different dimensions of gender is the natural default or ideal. This assumption serves to support sexist and cissexist beliefs, which in turn serve as the basis for discrimination and misgendering (both intentionally and through ignorance or uncertainty) against trans individuals and against anyone who is gender nonconforming in some way. Thus, this expectation of alignment is a source of both confusion and justification as it relates to gender labels.

Societal conceptualizations of gender are often binary, and the gender labels that we use tend to reinforce these binaries. For example, labels are often framed dichotomously between female and male, feminine and masculine, and trans and cis. However, these binary constraints do not represent the full spectrum or experience of gender, nor do they encompass the range or variety of labels that people use to describe themselves and others. As one example, the popular social media platform Facebook allows U.S. users to choose from more than 50 different gender labels. Users in the United Kingdom can choose from over 70. Some of these labels reference cis identity (e.g., cis, cisgender, cis female, cis man, cisgender male, cisgender woman). However, the majority of the labels refer to binary and nonbinary trans identities (e.g., agender, androgynous, bigender, female to male, gender fluid, gender variant, genderqueer, MTF, neither, neutrois, nonbinary, pangender, trans, trans man, trans person, transfeminine, transgender, transsexual person, two-spirit). The fact that there are more labels to describe trans identities should not be seen as evidence that those identities are inherently more diverse or complicated. As the normative ideal, cis identities and experiences often remain unexplored and are, therefore, linguistically unmarked and unlabeled. Because cis experience represents our expected default, when someone's gender matches that label, they are rarely asked to explain or justify their experience. In contrast, trans individuals have to put words and labels to their gender in a way that defines their experience against the (cis) norm and in a way that justifies the validity or existence of their gender. Thus, labels are not merely neutral descriptors. Rather, they represent the way in which language reflects larger understandings and assumptions around gender and identity.

Language carries its own gendered connotations; in some languages, even objects are assigned different genders or gendered characteristics. Public facilities are also often labeled with specific gender designations, marking certain areas as appropriate for only women/girls or only men/boys, as is the case with public restrooms and locker rooms. When used in reference to people, explicit gender labels are primarily used to describe gendered characteristics or gender identities. Gender labels can be used by an individual to define gender for themselves,

to identify their own gender, and to signal their gender to others. Gender labels can also be used to describe and categorize the gender of other people. Gender labels thus can help people understand themselves and others and enable individuals to feel that they are part of a community with all those who share their identity. However, when gender labels are imposed onto other people, miscommunication and misgendering can also occur. The following sections discuss gender labels in relation to assigned gender/sex, legal gender/sex, and self-identification. For many trans individuals, the social negotiation of gender becomes complicated when other people's labels are given precedence over their own self-identification.

Assigned Labels

Gender labeling typically begins with *assigned gender/sex,* when it is determined that an infant is seemingly female or male. This labeling of sex is primarily based on the examination of genitalia, either at birth or in utero. Assigned sex is typically made official with a gender marker designation on an individual's birth certificate soon after birth. Thus, this designation takes on both social and legal significance.

Assigned sex quickly becomes associated with *gender roles and expectations,* beginning a lifelong conflation of the connection between sex and gender. Assigned gender/sex reinforces the grouping of people into the binary categories of female and male. In turn, assigned gender labels play a large role in an individual's life by determining how they are perceived and treated by society, including the opportunities that are available to them and the extent to which they are at risk for experiencing discrimination and violence. In essence, these gender labels shape stereotypes about gender that are both descriptive (e.g., beliefs about what girls/women and boys/men are typically like) and prescriptive (e.g., beliefs about what girls/women and boys/men should be like). Subsequently, this assignment will also shape how an individual relates to their own *gender expression* and *gender identity.*

Assigned labels for gender/sex reinforce the gender binary as natural and can limit self-exploration and personal identity formation around gender. Even with the acknowledgment from medical and academic researchers that there are more than two gender/sex categories (e.g., intersex individuals, cultures with third and fourth gender roles such as two-spirit people within Indigenous communities), assigned gender/sex imposes a gender dichotomy. Binary gender, coupled with alignment normativity, reinforces and normalizes both sexist and cissexist beliefs and thereby perpetuates cisgenderism.

Legal Gender/Sex

Assigned gender/sex establishes a record and history of legal sex, beginning with the gender marker on a person's birth certificate Their birth certificate can then be used to verify their name and gender marker for other forms of legal documentation, including their passport, driver's license (or other state-level identification), and Social Security card in the United States. A combination of these documents may also be used to establish an "official" gender marker for school and employment records, as well as for medical insurance.

Some U.S. state and federal agencies allow for the gender marker on some legal documents to be changed from one binary gender category to the other (i.e., M to F or F to M) after the individual has medically transitioned. A growing number of states also allow for a third, "X" gender option on birth certificates and driver's licenses. However, the process for changing gender markers on documents, where it is possible, varies across document type and geographic locale. This patchwork system often leaves individuals with different gender markers on different documents. Changing a gender marker from one binary category to the other often requires "proof" in the form of a letter from a doctor or therapist, or documentation of surgery, thus reinforcing the expectation of alignment normativity (i.e., that an individual's gender identity is only valid if it coincides with some legal determination of "biological" sex). Changing gender labels on legal documents can be a time-consuming and expensive process. In addition, having to show evidence of one's identity to others requires a trans person to out themselves, which increases their risk of discrimination and violence.

Gender Labels and Self-Identification

Along with gender labels being imposed on an individual (e.g., assigned gender/sex and legal

determinations of gender/sex), such labels are also often used as a means of self-identification. Chosen gender labels tend to be broader in range than the binary labels that are assigned at birth or legally ascribed. Self-identification reflects an individual's own authentic *gender identity,* which has traditionally been defined as how someone see their gender as female, male, both, or neither. Trans individuals may use traditional labels for their gender to reference female (e.g., girl, woman) or male (e.g., boy, man) identities. They may also use terms to reference their identification with both female and male (e.g., bigender) or neither (e.g., agender, neutrois). In addition, many trans individuals use gender labels to reference the fluidity of their gender (e.g., gender fluid, gender flux) or the nonbinary nature of their gender (e.g., nonbinary, enby, gender nonconforming, genderqueer). Other terms emphasize the experience of gender in relation to trans identity (e.g., trans woman, trans man, transgender), gender transition (e.g., male to female, transsexual), or status (e.g., woman of trans experience).

Because trans individuals use labels that define their experience outside the cis norm, they often employ multiple labels to describe their gender, feeling that one term does not capture the totality of their identity. Trans individuals may also "code switch," using different labels in different social contexts in order to navigate disparate situations. For example, identifying as a trans man among others in the trans community may be a way of signaling community inclusion and promoting an understanding of shared experience. However, using "woman" (without a trans modifier) when in a predominantly cis setting may effectively deemphasize trans identity in spaces where it is not necessary or advisable for someone to know that they are trans. The use of gender labels often happens strategically, with attention to audience understanding and personal safety.

Power and Possibility in Gender Labels

The reliance on, or insistence that, assigned or legal gender/sex is a more valid indicator of gender than an individual's own gender identity serves as the basis for both personal discrimination and systemic oppression directed toward trans individuals. Imposing gender labels on others is oppressive, as narrow definitions of gender can be used to restrict trans individuals' access to public spaces, criminalize their behavior, or otherwise reinforce their identity or experience of gender as nonnormative. This, coupled with cisnormative understandings of gender, contribute to the continued pathologizing of trans identities.

Language changes over time, and the evolution of gender identity labels reflects a progression in societal understanding of gender diversity. In addition, the proliferation of gender labels reflects an increased nuance in our understandings of gender diversity and underscores the notion that gender exists as a spectrum beyond the binary. An important way to communicate an affirmative stance and to convey respect is by using the gender labels, as well as the name and pronouns, that an individual embraces for themselves.

Gender Minority Stress

Minority stress broadly refers to the unique stressors that minority groups experience, above and beyond the general types of stressors that anyone may endure. For instance, work may be stressful for many reasons—including navigating relationships with coworkers, job performance and advancement concerns, or other reasons. When someone holds a minority status, there are likely additional stressors that may arise, such as concerns about microaggressions or mistreatment from coworkers or one's boss, concerns about company policies and whether there are inclusive nondiscrimination protections, or other stressors. Even the stressors that are general in nature may take on additional nuance when experienced as the member of a minority. As such, the general stressors could also be influenced by biases toward minorities, such as interpersonal relationships not only being affected by individual personality differences but also slight or overt displays of stigma. When applied to trans individuals, these unique stressors are termed *gender minority stress.*

This term, *gender minority stress,* is an extension of Ilan Meyer's work related to minority stress for sexual minorities who were cisgender. In recent years, other authors have detailed the gaps in the original framework and adaptations needed to better match the lived experiences of trans individuals, as well as unique stressors that may arise for gender minorities that were not included in the original model. Gender minority stress is particularly relevant for trans studies because these stressors help to explain health disparities that exist for trans people. Trans people, for example, experience higher rates of depression, anxiety, and suicidality compared with cisgender individuals. Gender minority stressors help to contextualize these mental health disparities so that the drivers of these health issues can be centralized rather than pathologizing trans individuals. This entry addresses minority stress theory and extensions to gender minorities, unique stressors for gender minorities, and key contextual factors for understanding gender minority stress.

Application of the Minority Stress Theory to Gender Minorities

Ilan Meyer's model of minority stress was specific to the lives of cisgender sexual minorities; subsequent researchers have adapted and applied this model to gender minorities. In this previously established framework, minority stressors were divided into distal and proximal stressors. Here, these stressors will be applied to gender minorities. *Distal stressors* refer to more overt acts of marginalization, such as experiencing discrimination, harassment, violence, and related events. Trans people may be faced with unique experiences such as being denied care by medical professionals related to their being transgender, being denied access to restrooms of the gender they identify with, and having their gender sexualized in ways that are demeaning during acts of sexual harassment. Research supports that these overt, distal stressors are common experiences for many trans people and that they happen with a striking frequency. Research also has shown that these overt displays of bias are associated with worse mental health outcomes. These distal stressors also have implications for trans people's access to resources to ensure their basic needs are met. For instance, many trans people may be fired from their jobs because of bias on the part of their employer, or they may have trouble securing employment due to discriminatory hiring practices. In these cases, such employment issues also have implications for trans people's livelihood, as these may place them at risk for poverty, homelessness, and food insecurity, or they may create barriers to health insurance coverage. Other distal stressors, such as being denied access to restrooms that align with a person's gender identity, have implications for access to education, employment opportunities, and health (e.g., avoiding restrooms may be associated with health problems, such as urinary tract infections and kidney infections). As such, exposure to these stressors can have a domino effect, leading to substantial challenges across a range of life domains.

Proximal stressors are often a product of social marginalization and, in general, refer to stressors

that may be related to a person's beliefs, expectations, or self-concept. One proximal stressor that manifests for gender minorities is internalized stigma, sometimes referred to as internalized transphobia or internalized genderism. Internalized stigma for gender minorities occurs when an individual adopts a negative view of trans people, coming to view themselves and their gender in a negative light, and holding bias toward other gender minorities. This internalized stigma is deeply rooted in societal stigma and interpersonal factors that perpetuate negative views of gender minorities. Although a proximal stressor, internalized stigma is driven by living within social systems that oppress trans people. Research shows that trans people report a range of stressors that may lead to internalized stigma, such as negative social rhetoric about the legitimacy of trans identities, social narratives that equate being trans with having a mental illness, and the general devaluing of the lives of trans people. These negative messages are perpetuated from many outlets, such as the media, family members, and many religious communities, and by structural policies that deny protections to trans people. As a product of exposure to these messages, gender minorities may come to feel negatively about who they are, expect rejection from others, delay coming out or affirming their identities, and come to blame themselves for oppressive experiences. Research also shows that internalized stigma is associated with an array of negative mental health outcomes, such as depression, anxiety, and suicidality. Furthermore, internalized stigma may vary across generational groups, with older trans individuals having less internalized stigma, possibly as a product of developing resilience in the face of social oppression.

Expectations of rejection are another minority stressor that gender minorities may endure when anticipating that others will hold negative views toward them or reject them. Research has shown that gender minorities may have increases in their expectations of rejection across a variety of settings, such as any circumstances where they may need to disclose their gender marker on identification documents (when this does not align with their gender identity or presentation) or in many interpersonal situations. When experiencing these expectations of rejection, research shows that gender minorities experience a rise in anxiousness, worries, fearfulness, depressed affect, self-loathing, anger, and hypervigilance about their safety.

Finally, there is the minority stress of identity concealment, which has been shown to be a particularly nuanced minority stressor for trans individuals. On one hand, it could be the case that a trans person has not disclosed their trans identity to others and has not affirmed their gender and thus may be initially disclosing this identity to other people. On the other hand, it could be that a trans person has affirmed their gender and they are not readily perceived by others as trans and may be in a situation of disclosing information about their gender history. Decisions about disclosure of a person's gender identity or gender history may happen in a multitude of settings and relationships, such as with peers, with family, at work, or with others. Research has shown that concealment of this information may be associated with worry, fear, anxiety, feelings of inauthenticity, sadness, and other types of negative affect. However, for some trans individuals, research also shows that concealing a person's gender history may be a way of affirming a person's current gender and that some gender minorities may experience disclosing this history as invalidating to their current sense of self.

Of note is that although many of the stressors that are described here are similar to those in the sexual minority–specific minority stress model, there are unique, nuanced considerations when applying these stressors to gender minorities. For instance, at the distal level, a high percentage of trans people encounters violence (e.g., research shows anywhere from 15% to 47%), discrimination (e.g., estimates of close to 50% across some studies), bullying (e.g., estimates up to over 80% in some studies), and other forms of violence, such as verbal abuse or harassment. Unique to trans people, these distal stressors are embedded within a broader sociopolitical context that continues to target this group in specific and novel ways. For instance, in many states across the Unites States, there are no policies in place to facilitate gender marker changes on state-issued identification cards, which places trans people at greater risk of being "outed" as trans to others. There are many other sources of structural stigma for trans people, such as noninclusive insurance policies and a lack of legal protections in many states that may place gender minorities at unique risk for distal stressors.

It also is important to note that trans people of color disproportionately experience these distal stressors compared with white trans individuals.

At the proximal level, there are other nuances when applying the minority stress model to gender minorities. For instance, trans people are often given the message by others in their social circles, via social media, and through political rhetoric that their identities are not valid or should be viewed negatively. This overwhelming amount of negative messaging about trans people may be internalized, resulting in internalized stigma. Although internalized stigma is not unique to gender minorities, the sources and pervasiveness of these messages are specific to the lives of trans people. Unique to people who are gender minorities, expectations of rejection can be influenced by a person's gender presentation or expression. Gender expression can fluctuate due to changes to one's gender presentation that may happen over the course of a social gender affirmation (e.g., changing one's name or physical appearance such as clothing or hair) and medical gender affirmation (e.g., hormones or surgeries to masculinize or feminize a person's body). Expectations of rejection may be heightened for trans individuals who do not adhere to traditional narratives of what it means to be a "man" or "woman" or for the many gender minorities who do not pursue or desire medical gender affirmation, including those who do not have access to these resources given the many barriers that exist. The gender presentation and gender identity of these groups may be at odds with societal norms that most people have internalized, thus influencing their expectations of rejection. For identity concealment, as outlined above, a person may not have told others that they are trans and experience stress related to whether or not to "come out." In other cases, a person may be perceived by others as their current gender identity and experience stress regarding disclosure of their gender history.

Extension of Minority Stress Theory

Research has shown that there are additional considerations needed to ensure adequate representation of gender minorities' experiences within minority stress frameworks. Researchers have somewhat extended this model to be more specific to the lives of gender minorities by taking into account the nuances related to identity concealment and adding in other stressors that trans and gender-diverse people experience. Most notably, Rylan Testa and colleagues (2015) developed the gender minority stress and resilience model. In their extension of minority stress theory, they added the minority stressor of *nonaffirmation,* which occurs when a person's gender identity is invalidated by others. Nonaffirmation could occur through a number of mechanisms, such as when a person is called by the wrong pronouns, when incorrect gendered language is applied to them (e.g., "sir" being used when this does not align with a person's gender identity), when being called a specific gender label that does not align with their identity, when called by a name that the person does not go by, or through interpersonal mannerisms that communicate an incorrect understanding of the person's gender. Others have defined some of these actions as misgendering and note that this can be harmful because it invalidates a person's sense of self and may place gender minorities in a situation where they are outed as transgender or are faced with concealing this aspect of their identity if they do not address the misgendering. Trans people report that misgendering happens on a frequent basis. Some research has even shown that being called by one's chosen name is associated with less depression and suicidality compared with not being called by one's chosen name.

Another unique gender minority stressor has been termed *transitioning identity stress,* referring to stress that may arise when gender minorities do not fit into gendered social expectations for their identity (e.g., when a gender minority person is read as being a gender other than their identity). This gender minority stressor has been associated with higher levels of cortisol at waking for trans men compared to participants not reporting this stressor. Other research has documented stressors that may similarly characterize tensions between a person's gender experience and social expectations. One such stressor has been termed *bodily hypervigilance* and refers to when trans individuals may be on edge about others monitoring their body or gender expression. Another stressor that may arise at this intersection between trans people and others' expectations is the internalization of cisgender gender norms. This internalization may

result in gender minorities feeling negatively about their body image.

An additional minority stressor that has been recently documented is *vicarious stress*. As a product of living in a social context wherein trans individuals are targeted on a regular basis and there is ample negative rhetoric about gender minorities, trans people may frequently encounter narratives of stressful experiences from other gender minorities or through social media and news outlets. As a product of these narratives and social representations of trans people's lives, a gender minority person may also experience a heightened sense of stress. Although research on this stressor is only recently emerging, some qualitative research has described associations with anxiety and negative mood states.

There have been several critiques of the existing literature related to minority stress. One critique is that the language of "minority stress" does not adequately acknowledge the systemic nature of these stressors, and thus describing these experiences as "marginalization stress" may be more descriptive and accurate. Another critique is that, most often, researchers apply the minority stress model developed for cisgender sexual minorities to gender minorities without critically evaluating whether this adequately captures the experiences of gender minorities. Given the centralization of this model even in trans-focused research, much work is left to be done to identify, define, articulate, and develop measures related to gender minority–specific stressors.

Contextualizing Minority Stressors

When examining gender minority stress, it is essential to understand the social systems that create and sustain these stressors. For instance, at the structural level, there are a variety of policies and legislative forms of oppression. According to tracking data, the number of legislative policies put up for vote across the United States to restrict gender minorities' access to restrooms (only to those that align with the gender marker on a person's birth certificate) has grown over the years. But, as of 2020, only one state—North Carolina—has succeeded in passing such a bill, and it had to be rescinded the following year after nationwide political and economic pressure. According to the Human Rights Campaign, there are employment nondiscrimination protections that include gender identity in 21 U.S. states and D.C., hate crimes legislation that includes gender identity in 20 states and D.C., and inclusive public accommodations nondiscrimination protections in 20 states and D.C. In addition, only 21 states and D.C. allow gender marker updates on both birth certificates and state-issued driver's licenses. In most of the United States, trans people have few or no protections, and in many places, the legislation that exists takes an active approach to oppressing gender minorities. This political landscape may look vastly different depending on the social context and country where a trans person resides. Although a full review of other social contexts is beyond the scope of this entry, it is critical that these social systems always be taken into account when considering the experiences of gender minorities.

There are direct interactions between these social systems and the individual experiences of gender minorities, including their exposure to stressors. For instance, being denied access to the restroom aligning with a person's gender identity or not having identification documents that align with a person's identity may place them at direct risk for violence and harassment. Thus, this social context can severely limit the safety of trans people and place them at risk for greater exposure to minority stressors. The individual experience of gender minorities cannot be separated from the social spheres individuals are living within. Furthermore, an intersectional viewpoint is critical when understanding the contextual drivers of health issues and exposure to minority stressors. For instance, systems of power and privilege related to race and class can compound the stressors that trans people experience when having multiple minority identities. These power systems also uphold one another and thus are inherently linked and may perpetuate exposure to gender minority stigma.

Conclusion

Gender minority stress refers to the unique, stressful experiences that trans people endure that cisgender people do not experience. These minority stressors are experienced in addition to the general stressors that anyone may encounter. As described, there is a range of gender minority stressors, from the more overt acts of discrimination and violence,

to the more subtle minority stressors, such as expectations of rejection and internalized stigma. Furthermore, current research is actively describing novel minority stressors that are only beginning to be detailed and measured in the empirical literature, such as transitioning identity stress and vicarious stress. Any of these minority stressors must be understood within ecological frameworks that contextualize them as related to systems of power and privilege that disempower and oppress trans people.

Gender Nonconformity

Gender nonconformity is an umbrella term that refers to gender expressions and/or identities that do not conform to conventional gender norms, which are contingent upon time and location

(e.g., what is gender nonconforming in one place or at one point in time may be conforming in another). Generally, this is rooted in how one's expression or behavior is perceived by others or in how a person perceives themselves within a given society, with its unique gender norms and stereotypes. The term is sometimes used to refer to cisgender (cis) people whose gender expression does not conform to gender stereotypes. To attend to this nuance, this entry briefly discusses understandings of gender nonconformity across history, life span issues, adverse experiences, and pop culture.

In the 2015 U.S. Transgender Survey, 27% of participants described their gender identity as gender nonconforming or gender variant. However, not all gender-nonconforming people identify as trans; hence, they may lie outside the target for that survey and thus not be included in its sample. As of 2020, the prevalence of gender-nonconforming people (both cis and trans) has yet to be determined.

Historical Roots

In 2014, *Time* magazine declared the "Transgender Tipping Point," which framed a cultural shift toward increased trans visibility and acceptance, as well as increased attention to topics related to gender and gender nonconformity. However, gender nonconformity has existed throughout history and across cultures. In *Transgender History,* historian Susan Stryker (2008) defines *transgender* as "people who move away from the gender they were assigned at birth" (p. 1). Gender nonconformity is included in this definition, although historians highlight that what is understood contemporarily as gender nonconforming may not have been gender nonconforming at the time.

Gender Nonconformity Across Time and Culture

The existence of gender-nonconforming expressions and identities in humans can be traced throughout history. For instance, *hijra* and *kothi* people have existed for thousands of years in India. Particularly, the ancient Sanskrit texts the *Kama Sutra* and the *Mahabharata* include references to hijras, who, prior to the British Raj, held a great deal of sociopolitical capital. In ancient Egypt, since only men were believed to be able to access the afterlife, women's burial processes involved being buried in masculine coffins (e.g., flattened chest, red skin, beards) and using masculine pronouns during rituals so women could access the afterlife. In Italy, the depiction of *femminielli* in *Il Femminiello* also provides a glimpse into positive perceptions of gender-nonconforming men in 18th-century Naples. In North America, Native American two-spirit people have, as early as the 1800s, been regarded as conduits between physical and spiritual realms.

From the 15th to 20th centuries, European colonization in Africa, the Americas, and Asia brought with it increased rigidity of gender roles and stereotypes. Scholars posit that, prior to the European colonialism era, the previous examples of gender nonconformity may have been conforming to third-gender gender roles and expectations. As of 2020, for many cultures around the world, gender-nonconforming expression and behaviors for people who were socialized as men or assigned male at birth are considered particularly deviant. There are many explanations for this, one of which is that patriarchal societies that rely on a binary gender system consider femininity to be threatening, such that those who will give up their male or masculine privilege are considered particularly weak (this concept is also known as hegemonic masculinity).

Academic and Medical Understandings

Research related to gender nonconformity is mixed. Since gender nonconformity is based on cultural norms and stereotypes, research around the world captures gender-nonconforming expressions and behaviors in varying ways.

Pathologizing Gender Nonconformity

The 1850s through 1960s saw the medicalization and pathologizing of trans people and of gender nonconformity, particularly in Western countries. Access to gender-affirming medical interventions required conforming to specific narratives that made it challenging for trans and gender-nonconforming people to find affirmation in society. These narratives included the feeling that one was "born in the wrong body," the motivation to transition from one side of the gender

binary to the other, and the desire to be heterosexual after transition.

The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*) holds an important role in the pathologizing of gender-nonconforming identities and expressions. Starting in the 1950s, trans people were diagnosed with psychiatric disorders that conceptualized their gender identities as mental illnesses. The nomenclature for these disorders included *transvestism, transsexualism,* and *gender identity disorder*. In 2013, the fifth edition of the *DSM* shifted toward acknowledging the distress experienced when one's personal sense of gender is incongruent with one's body and therefore adjusted to include a diagnosis of Gender Dysphoria—replacing Gender Identity Disorder. As of 2020, activists and academics continue to critique the *DSM* for including diagnoses that may be used to continue to pathologize gender-nonconforming identities and expressions. The diagnoses in question include Gender Dysphoria and Transvestic Disorder, among others.

Gender Nonconformity Across the Life Span

Research related to childhood gender nonconformity is mixed. Throughout the 2000–2010 decade, researchers began investigating childhood gender nonconformity in ways that capture modern understandings of gender nonconformity, although a more nuanced way of researching gender nonconformity did not start until after 2010.

One research area rife with debate focused on childhood gender nonconformity is transgender research. There has been controversy regarding whether gender-nonconforming children will "persist" with their perceived transgender identity and which children "desist" with their perceived transgender identity, with the language of persistence and desistance first noted in 2003. The *International Journal of Transgenderism* (now called the *International Journal of Transgender Health*) published a special section devoted to this issue in 2018. This issue featured scholarly work by Julia Temple-Newhook and colleagues (2018), who noted that four primary articles published since 2008 have contributed to a miscited statistic that 80% of gender-nonconforming children, who were deemed to initially be transgender, would not continue to identify as transgender into adolescence. The authors provide a critical lens on this research, indicating that childhood gender nonconformity and transgender identity have been conflated in the research. They note four critiques of the research: (a) the misclassification of gender-nonconforming children as transgender (when they were not transgender in the first place), (b) not acknowledging the social context for those who participated in the research, (c) not stating how old the participants were at follow-up, and (d) inability of researchers to follow up with many participants.

Prejudice, Discrimination, and Violence

Beyond a misunderstanding in empirical research about what gender nonconformity is and how it has been classified in research, research also focuses on a variety of experiences as noted by and about gender-nonconforming people. Most of this research concerns experiences of victimization, harassment, and prejudice.

Impact of Victimization

Research indicates that when people experience victimization or harassment owing to their gender nonconformity, some of the effects are stronger for some individuals than for others. Studies that confirm the impact of gender nonconformity on those assigned male at birth indicate that the psychological effects of victimization and harassment are particularly notable. Research on this topic indicates that the combination of strength of "same-sex attraction" with being a boy who is gender nonconforming contributes to greater distress from victimization; however, this finding is only noted in young and middle adolescence and decreases in late adolescence. Alternatively, in South Africa, a research study indicated that gender nonconformity did not contribute to distress in a group of Black cis men who have sex with men (as defined in the study); however, their findings indicated that internalized homophobia (and not gender nonconformity) contributed to distress.

Gender Policing

Although the research on gender nonconformity focuses primarily on victimization and mental

health, some research has also focused on how gender-nonconforming people have experienced restrictions or "gender policing" on their expression and gendered behaviors. Gender policing describes a process whereby someone forces or compels another individual to express their gender in socially conforming ways. For example, gender policing would include telling a boy to not wear a dress to school or forcing a person to engage in reparative therapy focused on gender nonconformity. Several studies report on the impact of gender policing, with most focused on the policing of feminine behaviors on cis boys. In one study, fathers attempted to masculinize their gender-nonconforming sons by having them engage in certain behaviors, such as watching heteronormative pornography and publicly objectifying women. Elsewhere, typical gender policing of gender-nonconforming children reportedly is exhibited through the removal of gender-"atypical" toys, telling children to wear clothing that is gender stereotypical, and telling children to police their own behaviors to reduce the discomfort of others. These restrictions on gendered behavior and expression have been found to be harmful, as research suggests that when GBQ men experience gender policing throughout childhood and adolescence, they also experience increased substance use and psychological distress.

Shifting Norms and Expectations

Like other social norms, gender expectations vary widely across time and culture. For example, in 2015, National Public Radio reported that up to 38% of husbands are househusbands, which might be considered gender nonconforming in a culture where women typically are housewives.

Pop Culture and Media

Despite the overwhelming focus on victimization, harassment, and prejudice in academic and nonacademic circles, gender nonconformity also holds significant influence and representation in popular culture. Pop culture products that feature gender nonconformity or that challenge gender norms and stereotypes have existed throughout history. A spike in portrayals of gender nonconformity has led academics and nonacademics alike to speculate whether current gender nonconformity may be considered gender conforming in the future.

As of the 2010s, there has been a rise in gender nonconformity across various mediums that has garnered the attention of Western audiences. Alok Vaid-Menon is a performance artist and writer whose activism centers on challenging gender norms in beauty standards and fashion. During the 2019 Business of Fashion Conference, Vaid-Menon spoke on the importance of "de-gendering" fashion as a way to challenge cisnormativity. Writer, director, and producer Joey Soloway has received critical acclaim for *Transparent,* a comedy-drama centered on a family with a parent who is trans. Maxi Glamour is a drag queen and multimedia artist who engages in civil rights activism and challenges mainstream art production and consumption. They host events that center gender expressions, gender identities, and drag performance artistry that is marginalized in mainstream drag. Puerto Rican trap artist Bad Bunny explores and celebrates gender nonconformity in his music video for "Caro" and has emerged as a prominent advocate for queer and trans rights. In 2019, actor and singer Billy Porter wore a fitted tuxedo jacket and velvet gown to the 91st Academy Awards and has emerged as a prominent fashion icon for his gender-nonconforming ensembles. *Visual kei* is a Japanese music genre that often employs gender-nonconforming and androgynous imagery. Jaden Smith is an actor and music artist who is known to challenge gender norms by mixing masculine–feminine aesthetics in his work and wardrobe.

Fashion and Clothing

The fashion industry plays an important role in individuals' ability to find clothes that match their gender expressions. For example, someone with a large chest may find it difficult to find masculine shirts that fit properly, a person with wide shoulders may struggle finding flattering dresses, and a person with a penis may not easily find supportive lace panties, to name a few. The latter part of the 2010s, however, saw a rise in gender-inclusive clothes in Western countries. Brands such as TomboyX, Radimo, and Lonely Kids Club carry items in diverse sizes and shapes and have explicit gender-inclusive mission statements.

Gender on Legal Documents

Reclassification of sex designations is a core issue for trans legal engagements, since gendered allocation of legal status determines access to life chances, resources, and opportunities for both trans and non-trans individuals. With the growing visibility of trans communities around the world in the 21st century, many jurisdictions are reforming their policies to better respect trans people's rights to personal autonomy, while other jurisdictions are trying to legislate trans people out of existence by defining sex in immutable terms, contrary to its predominant social meaning in legal applications. Reclassification, however, is not a new issue; it has existed at least as long as the differentiated legal status of male and female has existed, and it is likely to keep evolving. In 2020, different kinds of legal regimes for reclassification still exist, ranging from a complete ban to self-determination of both binary and nonbinary designations. Direct challenges to the legality of the administrative act of birth assignment have yet to emerge.

The main site for allocating gender on legal documents is through the designation at birth of "male" or "female." Birth assignment is an administrative act in which newborns are assigned a legal status that becomes a part of their legal personhood and/or civil status. This act is generally performed by a medical professional who examines the newborn's visible genitals, declares the child to be either "male" or "female," and formally documents this information. Gender expectations ensue from sex assignment, such that those assigned "female" are assumed to grow up to be women and those assigned "male" are assumed to grow up to be men. People who do not identify or experience themselves according to these expectations find themselves without accurate identification documents.

The importance of sex reclassification for trans people lies not only in the desire for recognition but also in the need to be safe from anti-trans violence and discrimination. Having access to proper identification has also been shown to be among the factors that can significantly reduce suicidality among trans people. Sex designation arises in many daily interactions, such as at schools and universities, financial institutions, health care providers, foster care facilities, prisons, and the many other bureaucratic sites where one needs to present an ID that includes a sex marker.

By assigning sex at birth and recording it on IDs, state institutions expose large populations to discrimination, violence, and harassment. Trans people who struggle through various forms of social exclusion, such as those who are racialized, disabled, or poor, are more directly exposed to these harms, as they are more in need of social services that are segregated, such as homeless shelters, and are more likely to be incarcerated in sex-segregated prisons, where they are often sent to administrative segregation.

In 2020, there are four main streams of law and policy: total bans on reclassification, medical intervention-based schemes, corroboration requirements, and gender self-determination. In addition, there is an emerging demand to recognize nonbinary gender markers, and a growing number of jurisdictions have added a third-sex designation to their policies. These different laws and policies can overlap, and sometimes a specific jurisdiction bounces between different options.

Some jurisdictions do not have any law or policy allowing for sex reclassification or explicitly prohibit such changes. A refusal to address the

needs of trans people is akin to claiming that they do not exist and reflects a fundamentalist belief in the "naturality" and stability of birth assignment. Yet, even within countries that prohibit sex reclassification, trans people find legal and illegal ways to acquire proper identification.

General medical requirements demand that one undergoes genital surgery, sterilization, and/or hormone therapy as a precondition for recognition. Even though some trans people desire these procedures, requiring medical intervention for legal recognition reflects a grave breach of the right to bodily autonomy. Mandating sterilization and genital surgery have been denounced in many jurisdictions as inhumane. Other general medical requirements, such as undertaking hormone therapy, have also been found unjustified by domestic and international jurisdictions.

Corroborative policies require that an external party, such as medical or legal authorities, validates that the applicant does indeed belong to the sex in which they wish to be reclassified. While corroboration offers a less pathologized avenue for legal recognition, these policies nevertheless harm autonomy by requiring an external party to validate subjective identification.

The "gold standard" of reclassification schemes is considered gender self-determination. These are laws and policies that allow for reclassification based solely on self-attestation of gender identity. From 2012, when the first such law was enacted in Argentina, there has been a visible global shift toward self-determination. Reclassifying sex is understood as something beyond regulatory state or social control, something that is highly internal and hypersubjective. Yet state responsibility for the assignment of sex at birth is not challenged under this model.

In the first decade of the 21st century, a growing number of jurisdictions have started offering nonbinary sex designations, allowing people to reclassify their sex as other than M or F. The most common option for identification that exceeds binary sex/gender categories is an "X." However, within a mostly binary classification system, the X marker is also problematic. Those who are gender nonconforming have a dire need for their ID to reflect their gender identity, as their presentation is constantly questioned. Yet the X marker may draw attention to their difference, paradoxically exposing them further. The X marker may make state surveillance of gender dissidents easier. Moreover, adding a third category fails to address the systemic harms of sex classification.

Even the most innovative reforms have yet to question birth assignment of sex itself. What is changing are the modes by which a shift from one stable category to the other is to be achieved. It changes from external to internal, from the body to the self, from binary to nonbinary. Yet these reforms have limited ability to address structural inequalities. Thus, it is quite possible that future trans legal interventions would focus on the administrative act of birth assignment itself.

Gender Panics

Gender panics occur in moments when biology-based ideologies of gender are disrupted, and cis people struggle to understand where real and imagined trans people fit in gendered categories. A form of policing trans bodies, gender panics are frantic reassertions of a "natural" male–female binary.

Across different social environments, including workplaces, restrooms and locker rooms, athletics, prisons, shelters, and feminist communities, these panics are, at their core, about upholding the logic of gender segregation.

Because gender-segregated spaces depend upon definitions of gender to determine who does or does not belong, these panics serve to reinforce, as well as restrict, access to gendered spaces, as determined by biology, legal identification, and/or self-identity. Such panics are particularly heightened regarding trans women's access to women's spaces. In this moment of ideological collision, the "woman" in women's space is understood through notions of *biology*—particularly the presence of a penis—not *identity,* which leads to three consequences. First, this results in many cis people believing that trans women are not actually women but, rather, men "pretending" to be women in order to access women's spaces and sexually harm "real" women. Second, these panics portray cis women as perpetual victims, inherently vulnerable and always in need of protection from unwanted (hetero)sexual violence, and construct men as perpetual violators—sexual aggressors or sexual deviants who are constantly looking for ways to attack women. Third, this places trans people, particularly those who do not pass as cis (i.e., are seen as trans), at heightened risk for violence in public spaces.

Take, for example, public restrooms. In the United States and other Westernized countries, multistall public restrooms are often segregated, such that there is a men's restroom and a women's restroom. The spaces are structured around this segregation, with men's restrooms featuring urinals and women's restrooms having only stalls, thereby furthering the assumption that people who enter these spaces have or do not have a penis. But when people whose gender does not seem to correspond to the space enter to use the restroom, insofar as they are seen as trans, others determine whether they belong in that space based on their gender presentation *as well as* what genitalia they are assumed to have. The ensuing gender panic—or better called "penis panic"—is based on a fear of allowing the "wrong bodies" in spaces deemed to be "for women only." As a result, such panics serve to renaturalize a sex/gender/sexuality binary on the basis of biology, wherein there are only two sexes that align with two genders and that these two groups are (hetero)sexually attracted to one another, thereby denying the legitimacy of trans and queer people's identities. By assuming that all men (or people with penises) are interested in women and will go to extreme lengths to have sex, this "penis panic" logic foments anxieties that permitting people with penises to be in the same restroom as cis women will increase their risk for sexual harassment and assault.

Although there has never been a reported case of a cis woman being attacked by a trans woman in a gendered restroom, the reverse happens frequently. Because biology is the determinant of gender in these environments, trans people, especially those who are gender nonconforming or who are thought to be trans, are at a high risk for violence in such spaces. *The Report of the 2015 U.S. Transgender Survey* found that 9% of trans people have been denied access to the gender-appropriate restroom, and nearly 24% were questioned about whether they were in the correct restroom in the year prior to the study. In addition, one in eight trans people had been verbally or physically attacked or sexually assaulted when attempting to access the restroom that matches their gender identity in the past year alone, with trans women of color and nonbinary individuals, in particular, experiencing these forms of violence at even higher rates. Because of having been harassed or assaulted or fearing it, many trans people avoid public restrooms. Among respondents to the U.S. Transgender Survey, nearly one third reported having refrained from drinking and eating so that they did not need to use a restroom, and 8% indicated having had a urinary tract infection or kidney-related problems from not going to the bathroom or "holding it in."

Although gender panics generally center on trans women and penises, these panics can affect all individuals who are gender nonconforming, including nonbinary and gender-expansive individuals, butch cis women, and feminine cis men. For instance, masculine-presenting cis women have been forcibly removed from women's restrooms because they were suspected of being trans, and effeminate cis men have faced ostracization and violence on the suspicion that they were "gay" because their outward gender expression was read as transgressing gender and sexual boundaries. Because access to gendered spaces and resources

may be based on different gender criteria—biology or self-identity—gender panics can arise in multiple arenas and cannot always be anticipated. Under the guise of "protection," gender panics reassert ideas about the gender binary; they assume that people with penises are assailants, trans women are men, and cis women are vulnerable. Ultimately, they deny trans people the ability to be safe in public.

Gender Pronouns

Gender pronouns are third-person pronouns that reference the gender of the person being spoken about. English stands among only a handful of human languages with gendered third-person pronouns. The most common English examples are she/her and he/him; if we are recounting a story about someone and use one of these pronouns in place of that person's name, a listener would infer that person's gender. This is an automatic, yet far-reaching inference that now informs the listener's interpretation of the story: whether its events are typical, or atypical, for people like that; how the person may have acted otherwise; what the listener themself might have done in that situation; and so on. Due to the gendered significance of pronouns in English, many trans people's social transition involves changing their personal pronouns and asking others to use these new pronouns in reference to them. This entry introduces several aspects of gender pronouns and their relevance to trans studies—namely, pronoun attribution, pronoun selection, and pronoun inquiry.

Pronoun Attribution

Every day as we move about the world, we infer the gender of dozens (or, in a big city, sometimes hundreds) of other people around us, usually without becoming conscious of doing so. Pronoun attribution becomes conscious when we fail to automatically select a pronoun for someone who we must speak about, which otherwise happens based on unconscious assumptions. In these moments, we are socially conditioned to read that person's body for "clues" that may assist with our attribution of (most often) a binary pronoun: she/her or he/him. This experience of being closely scrutinized is a familiar one for many trans and gender-nonconforming people, as well as the cause of considerable and sometimes debilitating anxiety. Trans women and men are often able to make changes to their physiological or gender expression (e.g., dress, grooming, voice, gait, mannerisms) that result in others automatically attributing their correct pronouns (i.e., she/her for a trans woman and he/him for a trans man); this routine attribution can be a source of profound gender affirmation, as well as safety in transphobic spaces. However, nonbinary trans people (who are not women or men) are often unable to make changes that would help others attribute correct nonbinary pronouns (e.g., they/them).

Part of the broader social innovation brought about by trans activism, gender expression, and gender identity protections in law and policy (where applicable) and the rise of gender-neutral

pronoun usage involves challenging the notion that someone else can readily know the "truth" about a person's gender and assume the pronouns they use for themself. In other words, society is coming to understand that "the pronoun I say for a person based on what I see" may not be the same as that person's gender. In many jurisdictions, gender marker changes on IDs no longer require a trans woman or man to pursue transition strategies that could make correct pronoun attribution "easier" for others. Furthermore, in this historical moment, for trans people who are not seamlessly either women or men (e.g., who are nonbinary), strangers are frequently unable to attribute gender-neutral pronouns, whether consciously or unconsciously, even as these may be correct.

Pronoun Selection

The idea that gender pronouns are a matter of selection is unfamiliar to many, due to the societal experience of pronouns as automatic and a simple reflection of the "truth" of someone's gender. However, everyone, whether trans or not, has experienced pronoun selection, typically by one's parent(s) at the time of one's initial sex assignment. When parents select a set of pronouns and communicate this selection to those who interact with their child, this process unconsciously enlists others in a gendered socialization regimen. An infant being called by the "wrong" pronouns tends to prompt a swift correction from parents, who are uncomfortable with their child being seen as a gender different from their assigned sex and who want to make sure that the child is socialized to the perceived appropriate gender. A cis youth or adult who continues to be misgendered, either mistakenly or maliciously, will feel discomfort as well, just as is the case for trans people.

Reflecting the rapidly rising number of nonbinary trans people, especially among younger trans people, gender-neutral pronouns are becoming more and more common. The most popular gender-neutral pronoun is the use of they/them in the singular, but there are numerous other neo-pronoun ("new pronouns") options, including ze/hir and xe/xem. "They are" is grammatical in Standard English when applied to a single person, although it has historically been applied to a person whose gender is not known by the speaker (e.g., "the person who knocked on the door when you were in the shower; they left before you could respond"). It can feel uncomfortable to say "they are" for a person who one *does* know, but this usage is recognized by all major dictionaries and style guides. Over time and with practice, however, this discomfort recedes, as this use of singular they/them enters one's vocabulary.

Pronoun Inquiry

As it is becoming more commonly known that pronouns cannot always be automatically attributed based on someone's appearance, it can become necessary to inquire about a person's gender pronouns. This can take the form of directly asking the person about their pronouns; however, given that automatic pronoun attribution is highly affirming for many trans *and* cis people, being asked can be discouraging. One can avoid using gender pronouns to refer to someone else by using their name or they/them pronouns until one knows that person's pronouns. One can also discover the appropriate pronouns for another person by listening to how others who know them well talk about them, asking individuals who know them well what pronouns the person uses for themselves, and looking for pronoun "signposts." "Pronoun signposting" or indicating one's pronouns in a public location, like one's office sign, business card, email signature, name tag, or social media profile, is a common way of sharing one's pronouns and, increasingly, an effort to normalize the disconnection between "what I see" and "what I say" as the truth of anyone's gender.

Gender Recognition Technology

Algorithmic methods are increasingly being used to identify and categorize human characteristics. A range of human identities, such as gender, race, and sexual orientation, are becoming interwoven with systems. This entry discusses the case of automatic gender recognition technologies that algorithmically assign binary gender categories. Based on previous work with trans participants in human–computer interaction (HCI), this entry examines the ways in which current gender recognition systems misrepresent complex gender identities and undermine safety. Future work can build on this foundation by conducting participatory design workshops with designers and potential users to develop improved methods for conceptualizing gender identity in algorithms.

Algorithmic Identity: Introduction and Background

Increasingly, designers and engineers are building and relying on algorithmic methods to identify and classify people. From recommending products, automatically detecting language, and personalizing interactions, these algorithms often have clear benefits. However, the news media are replete with scenarios in which identity classification may be problematic.

For example, engineers have created machine learning algorithms to categorize sexual orientation by extracting and analyzing facial features from images. This work has faced severe scrutiny for its potentially dangerous implications—such as potentials for surveillance of what the system categorizes as gay and lesbian individuals—and criticized for its likeness to the flawed concept of physiognomy.

Other algorithmic methods, such as risk assessments for determining recidivism rates, have been criticized for their racial biases against Black people. These racial biases have been found to occur even when racial parameters are not included in the data used to train algorithms, as anticlassification methods have also shown to produce biases against protected classes in algorithmic methods. The removal of identity from certain algorithmic system may not prove the best, most equitable solution.

These problematic examples of human classification share two things in common. First, they have ramifications for minorities, often putting them at risk. The increasing adoption of algorithms seems to amplify the risks digital footprints present for historically marginalized individuals. Second, the background behind these algorithms highlights a tendency for them to be developed in generic ways, abstracted from specific systems, interactions, or contexts of use.

To untangle these problems—and investigate potential solutions—researchers can focus on a specific application area that has been little explored: automatic gender recognition (AGR) algorithms.

The Case of Automatic Gender Recognition

Existing approaches to AGR use computer vision and/or voice recognition data to predict a person's gender on an exclusively binary determination: female or male. One exception includes a data set of trans faces captured from YouTube in an attempt to identify a single person across gender identity transition. Even here, however, the transition was conceptualized along a binary spectrum and specific to the effects of hormone replacement therapy (HRT)—to say nothing of the authors' suggestion that people might use HRT as a means to avoid biometric detection.

Previous work has already uncovered the inaccuracy of AGR technologies on trans individuals. But scenarios such as these highlight concerns beyond accurate classification categories. They reveal the limited consideration, or even awareness, of the lived experiences of trans people. The broader impact of these consequence reflects more than simply gender. It may also reflect assumptions about age, presentation, and racial characteristics—other intersecting identity categories societies view through a gendered lens. The decisions embedded within technological systems reflect a

set of values that can have negative consequences. That is to say, technology is not risk averse or neutral; it is safety critical and value driven.

Gender Roles

See Gender Functions.

Gender-Affirming Surgeries: Men, Bottom

Gender-affirming surgeries for men are generally divided into two categories: top surgeries and bottom surgeries. Bottom surgeries are those that are performed either to remove existing reproductive and genital structures or to create such structures. The most common bottom surgeries for transmasculine individuals are phalloplasty, metoidioplasty, and hysterectomy. Phalloplasty and metoidioplasty are surgeries that are used to create a neo-phallus. Hysterectomy is a surgery that is used to remove the uterus. It is often paired with an oophorectomy, surgery to remove the ovaries.

Many transmasculine individuals are interested in undergoing one or more gender-affirming bottom surgeries. In general, individuals with a binary trans male identity are more likely to express interest in these surgeries than those with a nonbinary trans identity. However, not all trans men are interested in undergoing bottom surgery.

Gender-Affirming Bottom Surgeries for Men

Gender-affirming surgeries are procedures that are used to make trans individuals feel more comfortable in their bodies. These procedures either create structures that affirm an individual's gender identity or remove structures that are visibly associated with their sex assigned at birth. For binary and nonbinary transmasculine individuals, gender-affirming bottom surgeries include both those procedures used to create the function and/or

appearance of male external genitalia (i.e., penis, scrotum) and those used to remove unwanted internal reproductive organs associated with being assigned female at birth (i.e., uterus, cervix, ovaries, and vagina). Transmasculine individuals may be interested in one or both types of surgery, although removal of the uterus is thought to be a necessary part of any gender-affirming surgery that eliminates the vagina as part of creating more masculine external genitalia.

Surgical Creation of Male External Genitalia

Two types of gender-affirming surgery can be used to construct masculine external genitalia, also referred to as *genitoplasty* (*genito:* sexual organs; *plasty:* alteration). One type of male genitoplasty, called metoidioplasty, uses the body of the hormonally enlarged clitoris as the shaft of the penis. Another type, phalloplasty, uses what is known as a "flap" to create a larger neo-phallus that is more likely to be suitable for sexual penetration. Both metoidioplasty and phalloplasty can be performed in multiple stages or as a single stage that incorporates multiple procedures.

Certain elements are common to both forms of genitoplasty. Urethral lengthening involves extending the urethra (the opening through which a person urinates) to the end of the neo-phallus. This makes it possible to pee while standing. Urethral lengthening is usually performed using a tube of skin created from the lining of the vagina or the labia minora. This tube is connected to the existing urethra and, if a phalloplasty is being performed, to the neo-urethra that is created as part of the phallus. Scrotoplasty is the surgical creation of a scrotum and is also a component of both types of genitoplasty. For transmasculine patients, the scrotum is created using the skin of the labia majora. Testicular implants can then be inserted into the scrotum once it is healed.

Metoidioplasty

In a metoidioplasty, the hormonally enlarged clitoris is used as the neo-phallus. The clitoral ligaments are released, which makes the clitoris extend further from the body. The clitoris is moved higher into a position more similar to that of a phallus. As noted above, urethral lengthening makes it possible to pee standing up. Altogether, this creates a small phallus that maintains presurgical sexual sensation and has native erectile function. Most people who choose metoidioplasty do not have sufficient length to penetrate a sexual partner, and this surgery is not recommended for people for whom penetration is a priority. It is possible to have a phalloplasty after a metoidioplasty, but the reverse is not true.

Phalloplasty

Phalloplasty uses a flap of tissue to create a large neo-phallus that is suitable for sexual penetration. The most commonly used flap is the radial forearm free flap, or RFFF. This is a large rectangle of skin that is harvested from the forearm. Ideally, the nondominant arm is used. However, some people have tattoos they want to preserve on their nondominant arm or have other reasons for using their dominant arm instead. The RFFF phalloplasty leaves a large, noticeable scar on the arm that the skin is taken from, which some people worry may be stigmatizing.

Other flaps that are commonly used for phalloplasty include the anterolateral thigh (ALT) flap, the latissimus dorsi flap, and the suprapubic flap. Each of these options has benefits and disadvantages. Many surgeons who offer phalloplasty offer only one or two flap choices, as different surgical techniques are used for the different options.

The phalloplasty procedure starts out largely similar to the metoidioplasty procedure. However, there are several differences. The first is that the skin is removed from the clitoris and the clitoris is embedded in the base of the phallus. This means that stimulating the base of the phallus will stimulate the clitoris, providing erotic sensation. One of the clitoral nerves may also be connected to the new phallus, depending on the surgeon.

The other big difference is that the neo-phallus itself is created out of the flap as a tube within a tube. This may be done in one or more procedures, depending on both the surgeon and the flap that is used. If a urethral extension is done, the neo-urethra is attached to the inside tube, which forms the penile urethra. The outside tube becomes the phallus. A glansplasty may also be performed at this time, or at a later time, to create the appearance of the glans penis.

In order to have an erection after a phalloplasty, a penile prosthesis must be inserted. This is usually done at least a year after the phallus is initially constructed. It is important for the phallus to be

healed before insertion and for sensation to have returned through the end of the penis. Having protective sensation throughout the penis makes it less likely that the penile prosthesis will erode through the penis before a problem can be detected.

Complications of Genitoplasty

The most common complications of genitoplasty are related to the urethral lengthening procedure. The majority of people who undergo either a phalloplasty or a metoidioplasty will experience difficulty with urination at some point after their procedure. This commonly takes the form of a urethral stricture or fistula. A urethral stricture occurs when the urethra becomes narrowed or blocked, preventing the flow of urine. A urethral fistula is when a hole forms between the urethra and the outside of the phallus, leading to leakage. Fistulas most often occur at the base of the penis, although they can form anywhere along its length. Both of these problems can generally be repaired with outpatient surgery, although they may recur.

There is also a high risk of complications associated with the implantation of an erectile prosthesis. This is true for both malleable, or bendable, prostheses and inflatable prostheses. Complications associated with erectile devices include mechanical problems, erosion of the device through the neophallus, and the device becoming dislodged. A substantial proportion of people who have inflatable prostheses implanted will need to have them replaced or removed over the course of their lifetime.

Removal of Internal Reproductive Structures

Many transmasculine individuals experience dysphoria about internal reproductive structures, such as the uterus and vagina, which are associated with being assigned female at birth. Others are interested in undergoing a type of genitoplasty that requires removal of the uterus and/or vagina as a prerequisite. There are several types of gender-affirming bottom surgeries that can be used to address these concerns.

Hysterectomy

Hysterectomy technically refers to only the removal of the uterus, although many surgeons routinely remove the ovaries at the same time. The uterus is the organ in which a fetus can be gestated, and it is the source of menstrual bleeding. While a hysterectomy is also a relatively common surgical procedure among cis women, it is considered a form of gender-affirming bottom surgery if it is used to address gender dysphoria. In addition, transmasculine patients seeking any form of genitoplasty where the vagina will be removed are required to have a hysterectomy.

Vaginectomy

Vaginectomy refers to the removal of the vagina. Many surgeons who offer phalloplasty or metoidioplasty with a urethral extension require that patients also undergo a vaginectomy. This is because some data suggest that removing the vagina reduces the risk of certain types of urinary complications after genitoplasty. Transmasculine patients may also wish to have their vagina removed if it is a source of dysphoria.

Oophorectomy

Oophorectomy, or ovariectomy, refers to the removal of one or both ovaries, the organs that produce both gametes (eggs) and reproductive hormones. Despite the fact that an oophorectomy is often performed at the same time as a hysterectomy, removal of the ovaries at the time of hysterectomy is not required. Individuals who are interested in maintaining the ability to produce gametes can choose to have a hysterectomy and leave one or both of their ovaries in place. This does not affect the dosing of gender-affirming hormones, and some transmasculine individuals have been shown to have viable gametes even after many years on testosterone.

Fertility Implications of Gender-Affirming Bottom Surgeries

Historically, guidelines for gender-affirming bottom surgeries have been stricter than those for gender-affirming top surgeries because of the fertility implications of these surgeries. Removal of the uterus means that an individual who has had a hysterectomy, either alone or as part of phalloplasty or metoidioplasty, cannot carry a pregnancy. Removal of the ovaries means that a person cannot contribute gametes to the creation of a pregnancy, unless they have previously undergone fertility preservation.

Fertility preservation for transmasculine patients is often both expensive and highly dysphoric, which has meant that relatively few undergo the procedure. Due to the fact that a hysterectomy typically also includes an ovariectomy, patients have frequently had to choose between maintaining their fertility potential and being able to access gender-affirming bottom surgery. As awareness grows about the option to maintain the ovaries at the time of a gender-affirming hysterectomy, transmasculine individuals may be able to postpone decisions about their fertility until after they have undergone any gender-affirming surgeries they desire.

Gender-Affirming Surgeries: Men, Top

Gender-affirming surgeries for men are generally divided into two categories: top surgeries and bottom surgeries. Top surgeries are those used to create a more masculine-appearing chest. Most transmasculine top surgeries take the form of masculinizing chest reconstruction, a process somewhat similar to a double mastectomy. Some nonbinary transmasculine individuals, however, choose to undergo breast reduction instead.

Chest Dysphoria

Many transmasculine individual experience chest dysphoria—discomfort related to having a chest/breasts that are perceived as feminine, either by the individual or by those with whom they interact. Having a larger chest can make it more difficult to present as male and may make it more likely that the individual will be misgendered by others. This can increase the risk of gender minority stress and result in depression, anxiety, and other negative health outcomes. To reduce the size of their chests, many transmasculine individuals bind their breasts. Binding can be a solution in and of itself, or a way to tolerate chest dysphoria until it is possible to access gender-affirming top surgery.

Binding involves compression of the chest to create a more traditionally masculine appearance. The technique that people use to bind, and the amount of time they bind, can have implications for the technique used for gender-affirming top surgery. In particular, there is a risk of loss of skin elasticity and even skin breakdown if moisture is trapped by the binder. There is also a risk that prolonged binding can lead to alterations of the shape of the chest wall, which, in rare cases, may remain noticeable after chest reconstruction.

It is more common for the skin changes caused by prolonged binding to affect the type of surgery needed to masculinize the chest. Individuals with small chests and good skin quality may be suitable for less extensive surgical techniques, like periareolar surgery. Such techniques preserve the sensation of the nipples and are accomplished with less visible scarring. However, in cases where there has been significant skin damage caused by binding,

individuals who would have otherwise been candidates for periaerolar surgery may need to undergo a double mastectomy instead, with its longer and more visible scars. In addition, poor skin quality caused by binding can also affect the size and appearance of postsurgical scars.

Gender-Affirming Chest Reconstruction

At its most basic, gender-affirming chest reconstruction involves removal of the breast tissue to create a flat chest. However, many surgeons offering chest reconstruction also perform chest contouring, as needed. Resizing and repositioning of the nipples to provide a more masculine appearance is also a component of some types of chest reconstruction. However, not all insurance companies will cover this portion of the surgery, and some individuals choose to forgo having nipples grafted back on after surgery due to the cost or other concerns. There are several common methods of chest reconstruction.

Double-Incision Mastectomy

Individuals who have large breasts, large nipples, ptotic (sagging) breasts, and/or skin quality concerns will most likely be candidates for a type of chest reconstruction referred to as double-incision mastectomy, with or without free nipple grafts. During a double-incision mastectomy, the nipple–areola complex is removed as a full-thickness skin graft. Then the surgeon makes one incision above the breast and a second incision below the breast. These two incisions are closed, leaving either one long scar, or two separate scars, at the height of the crease underneath the breast. Ideally, these scars fall along the crease on the underside of the pectoral muscles. At this point, the nipples can be made smaller and repositioned in a more masculine position away from the center of the chest. This technique is referred to as free nipple grafting because the nipples are removed entirely from the chest wall (free of the chest) before being repositioned and reattached. Because of the additional costs sometimes associated with nipple grafts, healing concerns, and other factors, such as personal preference, some individuals may decide not to have the nipples grafted back onto the chest, choosing instead to go without nipples or to have them tattooed on at a later date. After nipple grafting, patients should not expect to have sensation in their nipples, although some individuals do report that a level of feeling returns.

Periareolar Mastectomy

Individuals with smaller breasts and good skin quality may be candidates for periareolar mastectomy, also referred to as keyhole mastectomy (although this is a misnomer, as the keyhole approach technically involves a vertical scar). With this technique, an incision is made around part of the nipple, and breast tissue is removed through this smaller space. Because skin is not removed in this technique, it is not suitable for as many patients, and there is a somewhat higher rate of patients requesting a surgical revision than with double-incision mastectomy. This includes planned revisions to reduce the size of the nipple and areola after the initial surgery as well as unplanned revisions. Some surgeons also offer what is referred to as a concentric periareolar technique, in which a larger circle of skin around the nipple is removed, the nipple is resized, and then the skin is closed around the smaller nipple.

Chest Contouring

Chest contouring refers to procedures that are used to make a more traditionally male-appearing chest. These may include liposuction to remove extra tissue and reshape the chest, as well to eliminate the inframammary fold—the place where the breasts meet the chest. Chest contouring is not always paid for by insurance, even when gender-affirming top surgery is otherwise covered. Chest contouring can be performed as part of the initial surgery or as part of a revision.

Healing Process

Healing from gender-affirming chest reconstruction takes place in two phases. In the first phase, patients are sent home with drains. These are tubes that come out from the skin and allow fluid to drain out of the body, instead of collecting in the chest. Many transmasculine patients report that dealing with the drains, which remain in place for approximately a week after surgery, is the most difficult part of having chest reconstruction, as they

can be quite uncomfortable or even painful. After chest reconstruction, individuals cannot lift their arms above the shoulder or carry heavy objects for around 6 weeks. Therefore, it is important for individuals to plan for time off work and/or school, if needed. People who do not have highly physical jobs can generally return to work or school after 1 week, with some accommodations.

Gender-Affirming Breast Reduction

Some nonbinary transmasculine individuals have chest dysphoria but want to preserve the ability to present across a broader gender spectrum. These individuals may choose to undergo a gender-affirming breast reduction to decrease the size of their chest, rather than a chest reconstruction to achieve a fully flat chest. Reducing chest size can allow individuals to bind more comfortably, when they choose to, while still presenting a more feminine contour at times. Breast reduction can also allow people to maintain the ability to nurse an infant (breastfeed/chestfeed) in the future, unlike most forms of chest reconstruction.

Younger individuals and individuals who seek care with plastic surgeons who do not have experience with the trans community may also be offered breast reduction instead of, or as an intermediate step toward, chest reconstruction. In addition, some parents of younger individuals may be willing to agree to a reduction but refuse to consent to their child having a fully masculinized chest.

Although it is possible to perform a chest reconstruction after breast reduction, the procedure can be slightly more difficult. Individuals seeking a chest reconstruction after previous breast surgery should ask how the earlier procedure will affect their results, including scar placement.

Puberty Blockers and Gender-Affirming Top Surgery

Not all transmasculine individuals are interested in gender-affirming top surgery. In addition, some transmasculine individuals do not need gender-affirming top surgery in order to achieve a male chest contour. Breast growth is determined by the ratio of estrogen to androgens, such as testosterone, in the body. Therefore, individuals with low estrogen and/or high testosterone do not develop breasts. This is why most cis males do not experience breast growth—they have high testosterone levels compared to estrogen. That is also the case for transmasculine youth who have the opportunity to start puberty blockers before there is any significant breast growth. They generally do not experience a period of time with a high estrogen-to-androgen ratio and, as such, do not develop breasts. Thus, top surgery is usually unnecessary for individuals who transition directly from early puberty blockers to gender-affirming testosterone treatment.

Satisfaction With Gender-Affirming Top Surgery

Research suggests that most people who undergo gender-affirming top surgery are very satisfied with their results and that regret is extremely rare. Gender-affirming top surgery is considered medically necessary because of its ability to improve the quality of life of transmasculine individuals across both physical and psychological domains. Transmasculine individuals have reported a number of improvements in their well-being after top surgery. Some improvements are related to individuals' increased comfort in how they are perceived by others, without the need to bind their chest. These may include greater comfort participating in activities, such as swimming, going to the beach, and exercising. Other improvements are more about individuals' comfort when interacting with their own body, such as when bathing, showering, and engaging in other hygiene and self-care activities.

Transmasculine individuals also report that top surgery reduces the extent to which they are misgendered. Being seen correctly for who they are both increases their safety and decreases the experience of gender dysphoria. By reducing gender dysphoria, access to gender-affirming top surgery has been shown to increase overall quality of life. This includes improvements not only in body image but also in overall mental health, physical well-being, and sexual health.

Gender-Affirming Surgeries: Women

There are a number of gender-affirming surgeries available for women. The most common gender-affirming surgeries include vaginoplasty, breast augmentation, hair removal, facial feminization surgery, and tracheal shave/thyroid chondroplasty. Not all transfeminine persons are interested in all, or any, of these surgeries. However, the 2015 United States Transgender Survey found that 95% of trans women either wanted to have, or had already had, vaginoplasty. This entry first describes the various techniques used for vaginoplasty and explains their relative merits, then describes the procedure for bilateral orchiectomy, the removal of both testicles. Next, the options for breast augmentation, body contouring, and hair removal are discussed in turn. The entry continues with a description of facial feminization surgery and the procedure called tracheal shave, which is used to reduce the size of the Adam's apple; the entry concludes with a discussion of vocal cord surgery, which is used to raise the pitch of the transfeminine person's voice.

Vaginoplasty

Gender-affirming vaginoplasty is the surgical creation of a vagina and vulva to affirm the gender of a transfeminine person. The goal of vaginoplasty is usually to provide external and internal genital structures that are aesthetically and functionally similar to those of a cis woman. However, some women are only interested in having an aesthetic vulva and are not concerned about the ability to experience sexual penetration. These individuals may choose a zero-depth or minimal-depth vaginoplasty. A number of different techniques can be used to create a neo-vagina for a trans woman, and new surgical procedures continue to be developed.

Penile Inversion Vaginoplasty

Penile inversion vaginoplasty uses the skin of the penis and scrotum to create the neovagina and the labia. It can be performed as a single surgery or in multiple, staged procedures. During penile inversion vaginoplasty, the glans of the penis is kept connected to the nerves and blood vessels but reshaped and moved down to create a clitoris that maintains erotic sensitivity. A cavity is created between the vagina and rectum. The skin of the penis is removed and inverted to create the lining of the neovagina, using some scrotal skin, if needed, for depth. The remaining scrotal skin is used to create the labia majora, and part of the urethra can be used to form the labia minora and internal walls of the vagina to give a pink, mucosal appearance.

Vaginal depth varies, depending on three characteristics of the patient: the size of their penis and scrotum, the elasticity of their skin, and their pelvic structure (which determines the size of the cavity to house the new vagina). A patient who has undergone hormone blocking to prevent an unwanted puberty may have genitalia that are too small to provide sufficient skin to line the neovagina. Therefore, penile inversion may not be their best choice for vaginoplasty.

Regular dilation is required after penile inversion vaginoplasty. Dilation involves inserting a silicone or metal rod into the vagina to keep it from collapsing and to maintain vaginal depth and width. Immediately after vaginoplasty, women must dilate multiple times a day. Over time, the dilation frequency decreases, but dilation is a lifelong commitment.

There are some concerns specific to penile inversion vaginoplasty. Prior to penile inversion vaginoplasty, patients must remove hair from the penile shaft and the scrotum to prevent any hair growth inside the vaginal canal, which can cause infection. In addition, they also must use lubricant for dilating and vaginal intercourse, as penile skin is not self-lubricating.

Intestinal Vaginoplasty

As with penile inversion vaginoplasty, intestinal vaginoplasty uses the glans of the penis to form the clitoris and the scrotal skin to form the labia majora. Where it differs is that intestinal vaginoplasty uses part of the sigmoid colon to form the vaginal lining. The surgery is also sometimes referred to as a sigmoid vaginoplasty. Dilation is still usually required after intestinal vaginoplasty but less intensively than after penile inversion. The tissue is self-lubricating and has more elasticity than penile skin. Because of this, penetrative intercourse may be easier. Some patients complain, however, that they have excessive, or smelly, discharge after an intestinal vaginoplasty.

Peritoneal Vaginoplasty

There has been a growing interest in peritoneal vaginoplasty, which uses the peritoneum—the lining of the abdominal cavity—to line the vaginal cavity. Although this technique is relatively new, it has several potential advantages over other types of vaginoplasty. Unlike with intestinal vaginoplasty, there is no concern about bowel repair or function, and unlike with penile inversion vaginoplasty, there is no concern about hair growth in the vagina. However, there is less information about long-term outcomes of peritoneal vaginoplasty than with those other techniques. As with penile inversion vaginoplasty, patients need to dilate and use lubrication after this procedure.

Zero-Depth/Minimal-Depth Vaginoplasty

Zero-depth/minimal-depth vaginoplasty is primarily an option for individuals who are too medically compromised to undergo a major surgical procedure, who are certain they do not want to experience sexual penetration, and/or who do not want to maintain their vagina with regular dilation. This type of vaginoplasty creates the external genitalia (i.e., clitoris, labia majora, labia minora) using the same methods as for the other types of vaginoplasty. However, the surgery does not create and line a vaginal cavity or creates only a minimal opening. This provides the external appearance of female genitalia and includes a clitoris that can experience sexual sensation, but the patient has no functional vagina.

Bilateral Orchiectomy

Bilateral orchiectomy is surgical removal of the testicles, the organs that produce both testosterone and sperm. Although orchiectomy is often done as a component of vaginoplasty, it can also be performed as a stand-alone surgery. Excision of the testicles removes the primary source of testosterone in the body. This allows transfeminine individuals who are receiving gender-affirming testosterone therapy to lower their estrogen dose and stop taking any testosterone blockers, such as spironolactone. Individuals who might be interested in having biological children need to preserve sperm prior to bilateral orchiectomy.

Breast Augmentation

Breast augmentation involves the use of breast implants or fat grafting to increase breast size. Although not all transfeminine individuals are interested in breast augmentation, many find that the breast growth they experience when on gender-affirming hormone therapy is not sufficient to make them feel comfortable in their bodies. Individuals assigned male at birth who went through puberty in their assigned sex have naturally broader chests than those assigned female at birth. They typically need a larger cup size than cis women to allow for their bodies to be in proportion. Furthermore, transfeminine individuals have thicker chest muscles. This means the skin around

their breasts is tighter, which makes it more difficult to insert large implants. Patients may need to have tissue expansion prior to implants being inserted. Larger chest muscles can also push on implants, increasing the risk of them moving out of place. The size of implant used in gender-affirming breast augmentation depends on multiple factors, including patient height/weight, chest height/width, the amount of breast tissue present, and patient preference.

Types of Breast Implant

Breast implant materials include silicone gel and saline, although all implants now have a silicone polymer outer shell to lessen the chance of accidental rupture. Silicone implants are firmer, feel like natural fat, come prefilled, have a smooth surface, and come in both round and teardrop shapes. They are often preferred for subglandular placements, above the chest muscle. Saline implants are rounder and more fluid-feeling. They are generally less expensive than silicone implants and require a smaller surgical incision because they are filled with saline at the time of surgery, after being put in place. They are usually best for subpectoral placement, underneath the chest muscle.

Body Contouring

Body contouring with liposculpture is the transplant of fat tissue from other parts of the body. It can be used for breast enhancement, but it is less widely used than breast implants. Body contouring is more commonly used to feminize other areas of the body, including the abdomen, hips, and thighs. Body contouring, also referred to as fat grafting, is not suitable for all trans women due to the fact that many do not have enough fat stores.

Hair Removal

Patterns of hair growth differ by gender due to the influence of testosterone. As a result, transfeminine individuals who have gone through a testosterone-dominant puberty may need to seek out permanent hair removal to affirm their gender. Common areas from which transfeminine people seek permanent hair removal include the face, chest, and back. This type of hair removal is rarely covered by insurance companies. In general, insurance companies that cover hair removal will only do so if it is necessary for a surgery, such as vaginoplasty.

Two methods of hair removal are considered to be effective long term: electrolysis and laser treatment. However, only electrolysis is considered permanent hair removal by the Food and Drug Administration (FDA). Electrolysis uses electricity to destroy individual hair follicles and can be used for people with any hair and skin color. It takes longer than laser hair removal, because it is performed follicle by follicle, rather than on an area containing multiple hairs. Laser hair removal uses light to destroy hair follicles. It is most effective for individuals whose hair is substantially darker than their skin tone. Data suggest that laser hair removal is sufficient when individuals are preparing for vaginoplasty.

Facial Feminization Surgery

Faces are perceived as masculine or feminine on the basis of a number of characteristics. *Facial feminization surgery* (FFS) refers to a wide variety of procedures used to give the face more feminine contours. These procedures include lowering the hairline, hair transplant, reshaping the forehead, rhinoplasty, reducing the height of the upper lip, and chin and jaw feminization. The particular set of procedures used will vary for each patient and for each surgeon. Given the importance of facial appearance in social interactions, facial feminization surgery can lead to a significant improvement in a patient's gender dysphoria and their ability to move through the world without being misgendered.

Tracheal Shave

Tracheal shave, or thyroid chondroplasty, is surgery used to reduce the size of the Adam's apple. Sometimes this surgery is performed as a component of facial feminization, but other times, it is performed on its own. The thyroid cartilage, also referred to as the Adam's apple, increases in size in response to testosterone. Therefore, it is larger in cis men than in cis women, and it can be a source of gender dysphoria in trans women.

Vocal Cord Surgery

Trans women who experienced a traditionally male puberty may risk being misgendered if their voice has a deeper, more male-sounding pitch. This can particularly be an issue when speaking on the phone, where there are no visual cues. Voice therapy alone can be an effective intervention for some individuals, allowing them to address the pitch at which they speak, vocal mannerisms associated with gender presentation, and other gendered communication components, such as breathing style, resonance, intonation, inflection, and word choice. However, some transfeminine people do not feel therapy alone can adequately meet their needs, and they pursue feminizing vocal cord surgery as well. This procedure shortens the vocal cords so they vibrate more rapidly and emit a higher, more feminine-sounding pitch.

Genderism

Genderism is the cultural belief or ideology that gender nonconformity or incongruence is negative. It is a bias that results from believing that gender is a binary construct, that someone is either a man or a woman. This ideology is now widely understood as oppressive and harmful, not just to gender-nonconforming people but also to gender-conventional people because it limits their ability to assume different gender roles. Genderism is not equivalent to transphobia, which is more of an interpersonal construct. In contrast, genderism is a cultural phenomenon existing mainly at the level of ideology, institutions, society, and culture. Although the term *genderism* has been used since the 1970s in sociology, it was mostly used as a gender-based alternative to *sexism;* the current use of the term to refer to anti-trans prejudice emerged in the mid-2000s.

Disambiguation

The definition of genderism in online dictionaries lacks specificity and cross-references the term with *cisgenderism*. The use of *genderism* in Trans Studies must be disambiguated from its use in popular political discourses in Europe, where it refers to how gender is socially constructed in ways that challenge traditional beliefs about gender, sex roles, and sexuality. Its antithesis, *anti-genderism,* is a populist movement that has pushed back against feminist efforts to bring about change. Because of this and other historical uses of *genderism* outside of Trans Studies, *cisgenderism* is becoming a less ambiguous term to use.

Popular Usage

Genderism, as a term to describe anti-trans prejudice, was first used to characterize the way in which trans people were excluded from the Employment Non-Discrimination Act (ENDA) in the United States in 2007. Mistakenly believing that the legislation would be more likely to pass Congress if it was limited to discrimination on the basis of sexual orientation, LGB legislators, with the support of some LGB advocates, removed gender identity protection from the bill. More recently, the term *genderism* has been used in the discourse

around proposed state laws that require people to use the public restrooms that match their legal sex. These so-called bathroom bills are premised on the false notion that there are only two sexes, which are determined at birth, readily distinguishable from each other, and immutable.

Academic Usage

Research in the social sciences on genderism typically uses the Genderism and Transphobia Scale developed by Darryl Hill and Brian Willoughby, which measures three related concepts of anti-trans prejudice: genderism, transphobia, and gender-bashing. Although many researchers focus on transphobia and do not often distinguish between transphobia and genderism, their work shows that genderism and gender-bashing are widespread across certain countries in Europe (the Netherlands, Portugal, Spain, Italy, and Poland), North America (Canada and the United States), South America (Brazil), the Middle East (Turkey), and Asia (China and the Philippines). Ideally, studies of genderism should be cross-cultural, but researchers often change the scale composition, thus altering its integrity, and translations are not always equivalent. In general, research finds that, across societies, cis men are more genderist than cis women, and trans women often face higher levels of genderism than trans men. The interplay of racism, heterosexism, and other forms of oppression means that trans individuals with multiple minoritized identities, such as poor trans women of color, generally experience greater and more extreme forms of genderism.

Scholars in the humanities often use intersectional frameworks for their analyses, showing how race, gender, and class influence societal attitudes toward trans people. For example, they consider how Chaz Bono, a white trans man, was perceived more favorably when he appeared on *Dancing With the Stars* than were the Black trans women who competed on *RuPaul's Drag Race,* and how Caitlyn Jenner has generally received more positive press coverage than Laverne Cox, not just because the former is white and the latter African American, but also because of socioeconomic status and possibly age. Unfortunately, few studies examine the intersections of genderism with age or with physical or mental ability. Such research would likely show that younger trans people and trans people with disabilities experience genderism more frequently because they are seen as less capable of thinking for themselves, including recognizing their own gender identities.

Institutional Evidence

Genderism is also very apparent in social institutions. For example, researchers have documented how professional discourses marginalize and misgender gender-nonconforming children, as well as how prisons and migrant shelters fail to recognize nonbinary genders. Studies of K–12 schools and colleges likewise find that nonbinary trans students are rendered invisible by institutional practices that are based on a gender binary and that fail to enable students to indicate the names and pronouns they use for themselves. Institutional genderism is particularly evident in high school and college sports teams and campus residence halls, because they focus on a person's sex assigned at birth and often make no accommodations for nonbinary students. Researchers are not only calling attention to and challenging these forms of anti-trans prejudice but also recommending institutional practices that are more gender inclusive or that entirely dispense with gender classifications.

Researchers from non-Western countries are just starting to address genderism. For example, scholars in China and Hong Kong have begun debating the genderism evident in their schools at both interpersonal and institutional levels. China has not enacted protections for trans students, which is seen as a consequence of the lasting influences of Confucianism, which stresses binary gender roles and the importance of heterosexuality.

The Future of the Concept

The concept of genderism is important because only by examining the ways in which gender is seen as a binary can this manner of thinking be debunked. But to be effective, discourses on genderism must include the experiences of nonbinary trans people and recognize how multiple, intersecting forms of oppression affect gender dichotomization.

GenderPAC

Founded in 1995, GenderPAC (Gender Public Advocacy Coalition) was one of the first national trans civil rights organizations established in the United States. Whereas most other trans groups focused on providing personal support to their members, GenderPAC's mission was to educate the public and advocate for laws against anti-trans violence and discrimination. During its 14 years of operation, GenderPAC was able to build congressional support for trans rights and paved the way for subsequent trans organizations to make further gains.

GenderPAC was formed inadvertently. In 1995 at "Be All You Can Be," an annual Midwestern trans conference, author and activist Riki Wilchins gave an impromptu speech about the need for trans people to see their oppression as a civil rights issue and become more politically active. Some members of the audience mistakenly believed that Wilchins was starting a trans rights organization and donated $1,000 to the nonexistent group. After consulting with other trans leaders, Wilchins decided that there was no reason not to actually create such an organization.

"GenderPAC" was suggested as a short, punchy name, even though the group was not a PAC or political action committee. Another $1,000 was collected for the group at a subsequent trans event, the annual Southern Comfort Conference, which demonstrated that interest in having such an organization was widespread in the trans community.

GenderPAC was formally established in November 1996 at a retreat in King of Prussia, Pennsylvania, where the crossdressing organization Renaissance, which served as the host, was located. More than 80 individuals attended, including representatives from Renaissance, AEGIS (the American Educational Gender Information Service), FTM International, IFGE (the International Foundation for Gender Education), It's Time America!, Tri-Ess (the Society for the Second Self), and the Intersex Society of North America. These other trans organizations effectively formed GenderPAC's board of directors.

Those assembled at the retreat decided that GenderPAC would focus on public education about trans people and passing legislation to address anti-trans hate crimes and employment discrimination. Attempting to tie together gender identity, sexual orientation, and racial oppression, GenderPAC's mission was to fight for "gender, affectional, and racial equality." Some white trans people saw the inclusion of race as tangential to trans rights, but many recognized the need to address the multiple oppressions that trans people of color face. Wilchins was confirmed as the new organization's executive director, and lawyer Dana Priesing signed on to direct legislative and educational efforts.

One of GenderPAC's main activities became lobbying members of Congress to pass antidiscrimination laws protecting trans people. At the time, lawyer Phyllis Frye, her wife Trish, and trans activists Karen Kerin and Jane Fee had been engaged in congressional lobbying for trans rights for several years. Wilchins had accompanied them on some of these visits, and the group decided that the inaugural activity for GenderPAC would be a National Gender Lobbying Day in 1995.

National Gender Lobbying Day

In the years before *Boys Don't Cry*, Caitlyn Jenner, and *Transparent*, many members of the public considered someone identifying as a gender different

from how they were assigned at birth to be bizarre and weird, and the idea of being a transsexual or crossdresser was still considered a perversion by psychiatry. Members of Congress were no different in their stereotypes about trans people. Few Congress people at the time knew anything about trans issues or even considered that trans people existed and needed to be protected by law. Even fewer, if any, had ever knowingly spoken with a trans constituent.

At the same time, few trans people were willing to be out, if they could avoid doing so, because they feared being subjected to violence and harassment and losing their jobs and families. Even trans people who were open about their gender identities were often reluctant to be known to the general public as trans and certainly did not want to call attention to themselves by lobbying Congress. Yet more than 100 trans activists participated in the First National Gender Lobbying Day, and they visited more than 200 congressional offices to advocate for trans rights laws.

The Lobbying Day was the lead story in the "National News" section of the *New York Times* the next day. This marked the first time that the *Times* had covered the experiences of trans people as a "hard news" issue, instead of relegating their lives to the "Style" or "Arts" section. It was a sign that trans activism had arrived.

GenderPAC continued to sponsor an annual National Gender Lobbying Day over the ensuing decade to push for passage of the Hate Crimes Prevention Act (which was enacted into law in 2009) and the Employment Non-Discrimination Act (which never passed). The lobby days also asked members of Congress to take the Congressional Diversity Pledge, in which they agreed not to discriminate on the basis of gender identity and expression in their offices. Nearly 200 congressional representatives eventually signed the pledge, including more than a dozen senators.

Other Trans Rights Advocacy and Efforts to Create a Wider Gender Rights Movement

Along with lobbying members of Congress, GenderPAC educated major corporate executives about the experiences of trans people and encouraged them to add "gender identity" to their company's equal employment opportunity (EEO) policies. In 1996, only six *Fortune* 1,000 corporations protected the rights of their trans employees. Through the work of GenderPAC, as well as trans employees lobbying their companies, more than 200 had enacted trans-inclusive nondiscrimination policies by the early 2000s.

Another major undertaking of GenderPAC involved issuing "50 Under 30: Masculinity and the War on America's Youth," the first detailed study of hate violence against trans and gender-nonconforming youth, in 2006. The report chronicled the murders of more than 50 individuals who were killed because of their gender identity or expression between 1996 and 2006; most were Black or Latinx, and almost all were trans women.

Wilchins advocated for a wider gender rights movement, which would include anyone who had experienced discrimination or violence because of their gender identity or expression. This stance increasingly led to friction with other trans leaders and with some GenderPAC board members, who wanted the group to focus solely on trans rights. The conflict led to the dissolution of the group in 2009. In its place, Wilchins created TrueChild, an organization that focuses on the ways that rigid gender norms negatively affect all young people.

GEOGRAPHIES

Trans geographies center the lived experiences of trans people across space and time by focusing on the relationships between trans people and the spaces and places of their everyday lives. The

field distinguishes itself from queer geographies and geographies of sexualities by directly centering trans people, communities, and experiences as sources of geographical knowledge and scholarship. Trans geographical work seeks to present new and original ways to analyze the nuances of how trans people interact with gendered spaces, normativities, and institutions, as well as the material experiences of trans people in specific geographical sites.

The Particularities of Trans Geographies

Geographical interventions ground trans studies in the everyday experiences of trans people in order to complicate and reject binary conceptions of gender in geographical scholarship. Importantly, trans geographies also align with other theoretical critiques of queer theory for its inability to capture and detail the material realities of trans people and its invisibilization of trans people through the use of *trans* as a disembodied category to explore philosophical concepts of gender. Inspired by Petra Doan's influential scholarship, trans geographies intervene in methodological discourses on the experiences and struggles of trans people in traditionally cis-centric research and scholarly settings. This area of trans geographies frequently implements autoethnographic methodologies to actively and reflexively challenge institutional power structures that often view trans people as the subjects of, rather than the producers of, academic research. Such narratives often parallel the seemingly countless arguments forwarded within the academy that generalize, erase, censor, and pathologize the experiences of trans people, many of which have been conceived and promoted by cisgender authors who fail to cite or center the work of trans scholars. Geography is no different. Far too often, we are viewed as subjects to be counted and mapped without consultation.

Gendered Spaces

One of the largest contributions of trans geographies rests in its elaboration of feminist geographical concepts of gendered spaces. Rather than understanding gendered spaces through a dichotomy of women and men, trans geographical work complicates how gender functions in, and creates, sociospatial processes with unique challenges for, and experiences by, trans people. In her critical 2010 intervention with "The Tyranny of Gendered Spaces," Petra Doan describes the everyday production of gendered spaces, from semipublic spaces like universities to private spaces such as homes. According to Doan, the tyranny of gendered spaces characterizes the ordinariness of gendered policing that becomes enforced both through individual bodies interacting in different spaces and social relations that police gender in the everyday spaces trans people inhabit. These strategies of governance instruct gendered experiences and meanings of belonging, as well as impede on trans people's everyday behaviors, forms of embodiment, and movement. While certain environments such as the workplace or clubs become gendered through sociospatial interactions, others are made concrete through social relations and unique geolegal structures, such as bathrooms or prisons. Notably, while trans people experience the impacts of these spatialized forms of transphobia more acutely, cisnormativity in public, semiprivate, and private spaces also affect gender-variant cis people.

One of the most overtly gendered spaces considered in trans geographical literature are bathrooms, which in many cases are upheld by legal jurisdiction and sociocultural impositions of gender. Gender variance among trans, nonbinary, and cis people becomes heightened in spaces where gender is regulated. In bathrooms, the notion of gender—and womanhood in particular—is frequently socially reinforced. For example, in the aforementioned piece by Doan, she explains through her autoethnographic research that after asking her employer for permission to use the women's bathroom, she was informed that she could not legally use women's bathrooms until providing court-ordered documents confirming that she had undergone gender confirmation surgery. In this context, the gendered meaning of women's bathrooms became both socially and legally reinforced to police the meaning of womanhood and the forms of embodiment, behaviors, and place-making associated with womanhood and femininity. Trans geographical scholarship reveals that transmisogynist policing, largely heralded by trans exclusionary radical feminists (TERFs), seeks to define womanhood based on one's assigned sex at birth, with devastating implications for trans women when

seeking women's-only spaces, including events like the Michigan Womyn's Music Festival or in bathhouses, often claiming physical attributes (such as genitals) as reasons why trans women should not be present. Such geographical interventions also identify that frequently, these forms of spatialized exclusion and ostracization unevenly target trans women, while trans men tend to be more welcomed at women's events despite being men.

Other routinely and strictly gendered spaces that have been explored in trans geographical work include jails and prisons (intersecting with carceral geographies, or the geographical study of spaces of state-instructed detention). Research on trans carceral geographies identifies key themes of how gendered spaces are governed and enforced in scales ranging from the body to the state (including distinctions between state and federal geopolitical structures) and the ways in which trans people become caught within (gendered) legal apparatuses. This work calls attention to the reinforcement of gender through spatial and legal means; for example, trans women in the United States are most often incarcerated in men's prisons and trans men in women's prisons, despite any gender-affirming physical changes they have undergone. Furthermore, carceral institutions and those who work for them (including correctional officers and managers, counselors, and medical doctors) have the power to ban access to gender-affirming clothing as well as transition-related health care access. In examining how gendered spaces define gender in a way to exclude trans people as Other, trans geographies reveal on an international scale how social relations and dynamics, the law, and cultural discourses of gender hyperpolice gendered spaces in violent ways, marking these environments as those in which hypervisibility greatly increases trans people's exposure to physical, legal, and emotional danger.

Charting Urban Trans Lives

Another site of trans geographical interest is that of queer urban spaces, with a strong focus on gay villages, bars and clubs, and bathhouses. Historically, queer spaces like these have served as environments in which trans people come into our own subjectivities and form community. Yet despite their antinormative sexual positioning and their utility by some trans people, queer urban spaces are also known to uphold gender normativities that isolate trans people. Following the Stonewall Riots in the United States, a push for acceptance and normalcy led to the majority of lesbian and gay communities adopting normative gender positions, and scholarship identifies how sexualized, hypermasculine imagery has become deeply entrenched in queer urban settings, leading to trans people of all gender identities and expressions feeling unwelcomed, unsupported, and invisibilized in such spaces. Trans geographies consequently critique how queer urban spaces reinforce homo/hetero binaries by establishing new gendered power differentials within queer frameworks that render queer urban spaces transphobic. Trans women are particularly targeted in queer spaces through the scrutiny and policing of feminine embodiment, as trans femininity threatens the stability of hypermasculinity in queer cis male spaces. While gender variance is more visible in queer spaces, transmisogyny informs an increased bias against, and contestation toward, trans femininity in such hypermasculine environments.

Despite the critique, gay villages can, and do, provide some support for trans people as a gateway into the LGBTQIA+ community and as a space that may offer more safety than those that are heteronormative. Trans people, including vulnerable youth, are reported to feel safer in queer urban neighborhoods despite experiencing discrimination by queer cis people. It is important to note that the majority—if not all—of the literature critically examining the experiences of trans people in queer urban spaces attends to metropolitan areas in the global North, leaving a large gap on urban trans geographies within the expansive category of the global South.

Trans Mobilities

Other scholarly work in the field of trans geographies seeks to map the mobilities and migrations of trans people, bodies, subjectivities, and political movements. This body of work sits between the fields of trans studies, migration studies, and trans geographies, emphasizing the role that state power, borders, and transnational geopolitics play in constructing trans narratives, along with the flows of trans bodies, subjectivities, and cultures.

Importantly, trans mobilities point to geographical notions of scale—particularly travel within (inter)national borders—and identify the important anxieties that emerge in encounters between trans bodies and mechanisms of state surveillance, biotechnology, and national security. Notions of health, for example, are deeply woven into critiques of how particular—often white and masculine—trans bodies can travel between, through, and across nations, revealing the ways in which trans embodiment intersects with anxieties of national health and race as contagion. Mobility across various public spaces is inextricably linked to one's perceived race, and racism goes hand in hand with experiences of misgendering, passive and overt forms of discrimination, misgendering, and violence—especially for trans women of color.

Narratives of gender transition are linked to the geopolitical mobility of trans bodies and subjectivities and reveal means of creating community while also troubling notions of "safely" returning to one's home (the concept of home pertaining to embodied, familial, and geopolitical meanings of belonging). The literal space of the home, for example, has been examined as a site of both recognition and illegibility for transmasculine people. Yet travel narratives and notions of safe return are frequently marketed and made relevant for white and class-mobile trans subjects, while trans migrants and trans people of color are hyperpoliced while moving both within, and across, nation-states. Geographical attention to trans mobilities enables critical examinations of the intersections between trans embodiment, cultures, and subjectivities as they relate to race and class, particularly as narratives of gender transition become increasingly incorporated into tourism.

Rural Trans Placemaking and Privilege

Alongside spatial explorations of trans mobility, trans geographical scholarship aptly identifies how whiteness in particular informs the rural spaces trans people can inhabit. For example, research finds that white trans men living in rural communities are able to more safely and securely access communities and live and work within rural settings by the sameness that is dictated by whiteness, while trans men of color often avoid rural settings. Rural understandings of masculinity, framed through working-class whiteness, structure networks of inclusion for white transmasculine people, while simultaneously reaffirming discourses and systems of white supremacy. Notions of trans masculinity in rural settings are troubled by trans geographies, signaling how trans embodiment comes into contact with the power of whiteness and other normative social structures, such as Christianity, and illustrating the trans (im)possibilities that are negotiated in rural spaces.

Trans Possibilities, Trans Survival

In the face of spatial exclusion, rejection, and hyperinvisibility, trans geographies bring light to the ways in which trans people find new ways of being. The Internet and digital geographies, for example, provide means for trans youth to connect with one another, forming networks of emotional support, mutual aid, and activism. Outside of virtual connectivity, temporary spaces through art projects and installations facilitate support and community-based knowledge production among trans youth, countering the ever-frequent discounting of trans people's identities and experiences. While trans geographical scholarship illuminates how profoundly space is used to prohibit trans embodiment, it simultaneously gives voice to the ways in which trans people insist on living and surviving within such precarious sociospatial conditions.

Trans geographies are spaces aptly defined and occupied by members of trans communities, including sites of activism that directly challenge the concept of gender binarism and biological determinism (the concept that one's gender is defined by chromosomes, genitals, and/or the sex assigned at birth) in society, politics, culture, law, politics, religion, academia, and beyond. Trans geographies identify the forms of underrepresentation and erasure outside of, and importantly within, the broader queer community. As well, trans geographies are spaces of enduring liminality, evolving to challenge ideas that processes of change and transition are inherently finite, as well as to endure shifting social and political climates that manifest in the unique, everyday spaces in which trans people live. This field of scholarship creates academic spaces that consciously center the work of trans scholars and reinforce their roles as necessary producers of

geographic knowledge, in a way that combats the inadequate and inappropriate forms of trans representation within the fields of feminist and queer geography by cis scholars. Trans geographies are everywhere.

H

Harassment

On the morning of February 24, 2020, Alexa Luciano Ruiz, a homeless Black and Puerto Rican trans woman, was fatally shot after being harassed for using a woman's bathroom. Ruiz's case is only one of over 2,343 murders worldwide of trans individuals between 2008 and 2016, with 165 bias-motivated homicides occurring in the United States. In 2019 alone, at least 26 trans individuals were murdered, 91% of whom were Black women, 81% of whom were under the age of 30, and 68% of whom lived in the South. The prevalence of hate crimes in this population may be underestimated given that there are no national surveillance systems tracking anti-trans homicides. In addition, many trans individuals underreport hate crimes to police because of real or anticipated transphobic maltreatment or stigma from law enforcers.

Trans individuals experience disproportionate rates of harassment and prejudice, including employment and housing discrimination, limited access to adequate and affirming health care, and bias-motivated violence. This population also faces harassment in the criminal justice system and in homeless shelters, as well as among service providers such as health care workers and law enforcement or criminal justice personnel. On a structural level, communities, institutions, and governments perpetrate transphobic harassment through the laws, policies, and social values that undermine those who do not present or identify within the hegemonic gender binary. Despite the high levels of harassment against trans individuals—particularly among young, low-income trans people of color—limited prevention, intervention, and response programs exist to address harassment facing this at-risk population. Trans people thus face harassment and multiple barriers to help seeking. As such, interventions have emerged to prevent or counteract the deleterious effects of transphobic harassment.

Conceptualizing Transphobic Harassment Within a Minority Stress Framework

In addition to *general life stressors* such as financial stress and divorce, trans individuals experience structural and interpersonal forms of harassment and discrimination directly related to their stigmatized gender identity (i.e., *minority or stigma-related stressors*). Harassment faced by trans people is rooted in anti-trans policies, laws, and other structural and institutional forms of violence against this population. Transphobic harassment includes exposure to negative identity-related events (e.g., gender-based victimization, rejection, discrimination, denial, and nonaffirmation) that seek to enforce hegemonic gender roles and norms and can take structural and interpersonal forms.

Structural Forms of Transphobic Harassment

Harassment faced by trans people is driven by state- and federally sanctioned structural violence

based on the stigmatization of gender nonconformity and perceived nonheterosexual sexual orientation, misogyny, and harmful norms around masculinity. Structural forms of harassment include policies, laws, societal norms, and environmental conditions that limit adequate access to resources among stigmatized groups of people, including trans individuals. Many institutions (e.g., schools, shelters, and prisons) operate within a gender binary, which can cause distress among trans people for a variety of reasons. For trans people who identify as women or men, for example, it is not always ensured that they can choose an environment consistent with their gender identity rather than their sex assigned at birth. For nonbinary individuals, choosing (or being forced into) environments designated for those who identify within the gender binary could be inconsistent with their gender identity or expression.

Other examples of structural harassment and discrimination include policies that restrict trans individuals' access to adequate health care coverage, limited gender-affirming training among service providers, and denial of gender-affirming health care. Even when trans people are adequately insured, accessing gender-affirming care can still be difficult as private insurers may deem gender-affirming medical interventions as medically unnecessary. Trans individuals who are not insured for gender-related care and who wish to medically and socially transition in order to live more authentically may resort to using unregulated and potentially contaminated street hormones or liquid silicone, leading to serious health risks. The medicalization of trans identities has contributed to endocrinological and surgical interventions that reduce the incongruence between sex assigned at birth and gender identity and expression for many trans people. At the same time, these same gender-affirming procedures often involve acquiring a formal psychiatric diagnosis of gender dysphoria.

Over the past decade, major changes around trans issues have occurred on an institutional level, including efforts to pass "bathroom bills," which would require people to use restrooms congruent with the gender marker on their birth certificates; the Obama administration's guidance to schools supporting trans students; and the Trump administration's reversal of Obama's trans-affirmative school policies. Other policy reversals that took place under the Trump administration included changes to administrative policies so that trans individuals were no longer protected from discrimination under federal law in employment, housing, health care, and adoption. In addition, trans people were barred from joining the military, which is especially significant because research shows that they are twice as likely as cisgender (cis) people to serve in the military. The Biden administration immediately began the process of rescinding the Trump era changes when it took office in January 2021, including announcing that trans people were covered under sex discrimination regulations in federal law and lifting the ban on trans people serving in the military.

Interpersonal Forms of Transphobic Harassment

In the United States, most trans individuals have experienced at least one form of harassment (e.g., verbal abuse and physical and sexual victimization) beginning in childhood. In fact, rates of harassment toward trans individuals have been steadily increasing since 2012. Trans individuals experience interpersonal forms of transphobic harassment in their families, romantic and dating relationships, religious and faith communities, schools, workplaces, transitional living programs, legal and health care systems, and the military. Growing evidence suggests that compared to cis individuals, trans individuals are more likely to experience bullying, verbal abuse, sexual assault, rape, dating violence, hate crimes, and threats of physical violence.

Many trans individuals—especially those who are gender nonconforming—may experience denial of one's gender identity or expression and ridicule for not adhering to societal expectations of binary gender roles according to their sex assigned at birth. For example, they may be harassed, derided, or questioned for not presenting as "feminine" or "masculine" enough or for not engaging in stereotypical gender-conforming activities. Many may experience threats to disclose one's gender identity/expression to others without consent. Harassment can also range in severity from subtle forms of discrimination that communicate insensitivity or hostility (i.e., microaggressions) to bias-based bullying and hate crimes. Microaggressions

directed at trans individuals include (1) utilization of transphobic and/or incorrectly gendered terminology, including pronouns; (2) endorsement of beliefs that all individuals who identify as trans are the same; (3) objectification, dehumanization, and tokenization of trans identities; (4) discomfort with or disapproval of trans identities; (5) endorsement of cissexist, gender-normative beliefs; (6) denial of transphobia; and (7) assumptions that trans individuals are pathological or sexual deviants.

Unique Considerations Across Various Groups of Trans Individuals

It is important to consider ways that harassment experienced by trans people may vary according to the intersections of multiple systems of privilege and oppression. This may involve examining how risk for or consequences of harassment vary across gender identities (e.g., people who identify as trans women, trans men, or nonbinary). In addition, it may require focusing on whether race, ethnicity, immigration status, or socioeconomic status influences the severity, frequency, and types of harassment encountered by trans people. Documenting similarities and differences in the manifestation and impact of harassment across diverse groups of trans people is critical to advancing intervention and prevention efforts for this community.

Common Forms of Harassment Faced by Binary Trans Men and Women

Trans women defy hegemonic gender norms and thus are at risk for experiencing structural and interpersonal violence and discrimination due to both misogyny and transphobia, or *transmisogyny*. That is, trans women are at risk for gender-based violence because of societal and structural bias against women, in addition to bias related to transgressing the traditional gender binary. Indeed, the devaluing of traditionally female attributes may contribute to male gender roles being more rigidly defined and monitored than female gender roles. The policing of masculinity relative to femininity can result in increased tolerance for individuals assigned female at birth to violate gender norms, as compared with those assigned male at birth. Furthermore, trans women of color and trans women who engage in sex work are at heightened risk for harassment compared to other groups of trans individuals due to interlocking experiences of systemic oppression (e.g., sexism, racism, classism, transphobia, homophobia).

Many universities and workplaces have not established gender-inclusive spaces or included language around gender identity or expression in their antidiscrimination policies. As a result, trans women often experience denial or refusal when accessing binary-gendered spaces, such as restrooms, shelters, and prisons, because of the need to "protect" cis women from "male predators." This specious argument not only conflates being trans with violence against cis women but also invalidates, dismisses, and renders invisible the gender identity and expression of those who are denied access. In addition, research suggests that trans individuals are more likely to experience harassment in public spaces than cis people.

Due to structural barriers and interpersonal stigmatization, trans women are more likely than cis individuals to experience unemployment and homelessness, both of which uniquely predict poorer health. Other research shows that trans women are more likely to face sexual and physical harassment in the workplace than trans men. Trans women who are undocumented, who identify as racial or ethnic minorities, and/or who identify as sexual minorities are particularly at risk for unemployment, poverty, and homelessness, owing to the combined influence of transphobia, sexism, nativism, racism, and heterosexism. Given the challenges these populations encounter attaining legal forms of work, they may turn to (currently criminalized) sex work to survive, which in turn puts this population at increased risk for HIV and other sexually transmitted infections (STIs), violence, and incarceration.

Trans men are more likely to report suicidality and psychological distress compared with cis individuals and other trans populations. Nevertheless, relative to binary trans women, less research has focused on binary trans men. Trans men face many of the same psychosocial stressors (e.g., homophobia, transphobia, racism, violence exposure, depression) that place cis men who have sex with men and trans women at heightened risk for HIV infection and high-risk sexual behaviors. Trans men

who report having a partner question or reject them based on their gender identity or expression are associated with an increased likelihood of engaging in condomless sex. Social gender affirmation from one's romantic or dating relationship or sexual partner oftentimes supersedes trans men's desire to protect their sexual health, particularly among those who have not socially transitioned.

Trans men may have unique experiences of harassment due to transgressing traditional feminine roles. For instance, many trans men report low rates of using gynecological services, including Pap testing, and cervical and breast cancer screening; this is variously ascribed to gender dysphoria; provider insensitivity, bias, and discrimination; and a history of abuse. Trans men also underuse preventive health care services (e.g., HIV/STI testing) owing to structural barriers, including lack of health insurance or noncoverage due to having a male gender marker on insurance documents. These rates are highest among trans men who have low income and those who identify as people of color.

Common Forms of Harassment Faced by Nonbinary and Genderqueer Individuals

People who identify their gender outside of the traditional binary (e.g., nonbinary, genderqueer) experience harassment in gender-based social systems and structures, including restrooms, social traditions, clothing stores, prisons, and legal documents. Similar to binary trans people (e.g., trans men and women), those who identify as nonbinary and genderqueer also face several financial barriers to receiving hormone therapy and gender-affirming surgeries due to lack of insurance coverage. Discriminatory practices and anti-trans policies may vary based on nonbinary and genderqueer individuals' sex assigned at birth or level of identity concealment. For example, nonbinary and genderqueer people who disclose their gender identity in the workplace report lower rates of unemployment but are more likely to be denied promotion than those who do not disclose their gender identity in the workplace. Together, these findings suggest that employers are likely to police nonbinary and genderqueer gender presentations and identities.

Nonbinary and Genderqueer People Targeted on the Basis of Gender Nonconformity

In addition to structurally sanctioned harassment, many nonbinary and genderqueer people also face interpersonal forms of harassment owing to gender nonconformity, such as invalidation through misgendering (e.g., misclassification of one's gender identity). Research suggests that nonbinary and genderqueer individuals face higher rates of anti-trans discrimination in general, specifically in health care settings and by police officers, than do their binary trans counterparts. Nonbinary and genderqueer individuals report higher rates of physical violence and sexual abuse in childhood and adulthood compared with binary trans people. Nonbinary and genderqueer individuals also need to frequently disclose their gender identity due to misgendering and policing, or they conceal their stigmatized gender identity by, for example, changing their pronoun usage or gender expression to avoid being targeted.

Many nonbinary and genderqueer identities and expressions are interpreted by cis and binary trans people as invalid or illegitimate because they transgress binary transnormative expectations (i.e., do not reflect the dominant transnormative binary narrative). Other common misperceptions about nonbinary and genderqueer people include that they are confused about their gender or that their gender identity is a stage that will result in a binary transition (e.g., from male to female). Indeed, others may have difficulty perceiving or referring to gender in nonbinary or genderqueer ways, which may contribute to systems and communities forcing nonbinary and genderqueer people into alignment with the hegemonic gender binary. As such, nonbinary and genderqueer individuals may report elevated rates of harassment compared to binary trans people given others' perception of a trans status.

Nonbinary and Genderqueer Individuals' Experiences With Health Care Settings and Interactions

Nonbinary and genderqueer people are also often misunderstood in gender-related health care settings, given that many health care providers (even those trained in trans care) lack the knowledge, training,

and experience to deliver affirming gender-related care. Many nonbinary and genderqueer individuals report that the type of medical care they seek does not mirror the binary transnormative narrative. For example, nonbinary and genderqueer people may achieve authenticity with a more flexible and expansive range of medical approaches, such as using smaller doses of hormone therapy and declining gender affirmation procedures. As a result, many nonbinary and genderqueer people are denied medical services and are instead referred to mental health treatment, which might reinforce pathologizing beliefs about trans identities. As a coping strategy, nonbinary and genderqueer people often "borrow" a binary trans label to access gender-affirming care and consequently feel inauthentic and misunderstood.

Transnormative social pressures (e.g., "striving for" binary trans identities that closely approximate cis ones) may become internalized and reinforced within the trans community. Nonbinary and genderqueer people contend with prevalent misconceptions that they are not "trans" enough. Due to misgendering and other problematic misconceptions of having a border identity, nonbinary and genderqueer individuals face unique challenges accessing social support from cis heterosexual, cis sexual minority, and binary trans communities, leaving many nonbinary and genderqueer people feeling a lack of belonging—a known risk factor for poor health. Over time, transphobic harassment can also compromise nonbinary and genderqueer individuals' access to internal coping resources (e.g., effective emotion regulation), thus contributing to depression, anxiety, and suicidality.

Health Consequences of Transphobic Harassment

Compared with cis individuals, trans individuals continue to face numerous adverse health outcomes, including hypertension, diabetes, substance use, HIV and other STIs, depression, anxiety, and suicidality. Consistent evidence suggests that trans individuals are placed at a high risk for mental, physical, and behavioral health issues, given their experiences with ongoing systemic and interpersonal trans-based discrimination and harassment. In fact, trans individuals at increased risk for suicidality and other co-occurring mental health issues (e.g., posttraumatic stress disorder [PTSD], depressive symptoms, and substance use) are those who have experienced family rejection; are younger, people of color, or low income; engage in sex work; and lack social support. Transphobic harassment often leads to low self-esteem and elevated levels of poor mental, physical, and behavioral health because of the ways in which chronic identity-related rejection can become internalized. For instance, trans individuals who experience identity-related invalidation may eventually believe that there is something wrong with them. In addition, many individuals experience transphobic harassment as traumatic, leading to symptoms of PTSD, such as hypervigilance and avoidance. Many trans people may begin to self-stigmatize—including wishing they were cis, concealing their gender identity or expression, or anticipating transphobia from others. Trans individuals who face stigma, discrimination, and trauma may use alcohol, marijuana, or other illicit substances to cope with transphobic harassment.

Barriers to Help Seeking Among Trans People

Trans people face many barriers to help seeking after experiencing harassment. Help seeking is often understood as a two-step process: First, the person who survives harassment identifies what occurred as problematic, then pursues assistance from individuals, organizations, and communities to find relief and care. Help seeking can include pursuing formal support (e.g., from domestic violence shelters, court orders, polices reports, or psychotherapy) and informal support (e.g., from friends, family, or trans community). Trans people face significant barriers to both formal and informal help seeking, due largely to a context by which they experience harassment, namely, a culture of transphobia and lack of recognition/validation.

One barrier is our limited understanding of the pervasiveness and consequences of harassment among trans people. This phenomenon is understudied, and our knowledge is limited by small sample sizes, lack of support, and constrained research methods (e.g., researchers using different measures to assess harassment; difficulty recruiting samples that are representative of the trans population). Second, anti-trans stigma is a significant two-way barrier: preventing trans people from seeking help and limiting the effectiveness of

support services. Trans people often experience internalized stigma and thus may not believe help is important or deserved. Stigma also tends to limit the availability of informal help, owing to family and peer rejection and limited community-based services. Third, stigma increases risks of help seeking, as trans people may be outed and thus may face future harassment. Fourth, structural inequity continues to be a barrier. Harassment response services tend to reinforce binary gender norms and center cis women. Transphobia also exists within police systems, reinforcing structural inequity in criminal justice responses to harassment and help seeking.

Improving Trans Individuals' Health and Well-being

The development and implementation of gender-affirming prevention and intervention efforts represents a critical public health need given that lack of access to medically necessary care can lead to depression and suicidality among trans people. It is also important to improve gender-affirmative training among service providers and law enforcers. Other needed structural changes to improve trans individuals' health include implementing policy-level protections based on gender identity and expression (e.g., nondiscrimination laws) and facilitating access to medical, social, and legal aspects of transitioning. Moreover, to promote resilience and access to health-promoting resources among trans people who hold multiple marginalized identities, it is critical to improve legal protections against discrimination based on race or ethnicity, immigration status, HIV status, income, sexual orientation, gender identity, and engagement in sex work.

Research suggests that delivering interventions in an effort to increase trans people's access to social support and stigma-related coping strategies might improve self-esteem and reduce the deleterious health consequences of transphobic harassment. Studies have also highlighted the positive health impact of socially, medically, and legally transitioning among binary trans youth. It is also important for trans people to feel supported and welcomed by other members of the trans community and trans support groups. Connecting with others also improves self-esteem and positive overall mental health. Finally, encouraging trans individuals to engage in activism may be empowering for this population and thus serve as an important buffer against poor health.

Conclusion

Transphobic harassment reflects and perpetuates society's devaluation of people whose gender identities or expressions do not conform to restrictive, cisnormative views of gender. The harassment trans people encounter manifests at the structural and interpersonal levels. Some manifestations of transphobic harassment—for example, expressing the view that gender identity must be identical to sex assigned at birth—may vary across binary trans women, binary trans men, and nonbinary and genderqueer people. In addition, transphobic harassment does not occur in a social vacuum but rather co-occurs with and is influenced by other systems of oppression, such as sexism, racism, nativism, classism, or heterosexism. Thus, trans people who experience multiple forms of marginalization—such as trans individuals living in poverty, undocumented trans men, or trans women of color—may be particularly at risk for experiencing or being negatively affected by harassment.

Substantial research has documented the associations of transphobic harassment with negative identity, mental health, and physical health outcomes among trans people. The negative impact of transphobic harassment and stigma on well-being is potentially exacerbated by the substantial barriers that many trans people face when accessing trans-affirmative health care, social services, or informal social support.

Improving the well-being of diverse trans people requires multiple forms of intervention. Health care providers must be aware of the deleterious influence of transphobia on the functioning of trans clients or patients and incorporate this insight into service provision. Programs and institutions must provide trans-affirmative training to enhance service provision for trans people. Educators and social justice advocates must inform the public and policy makers about the importance of not only combating transphobic laws and policies but also creating laws and policies that protect the rights, dignity, and well-being of trans people.

Health Care, Discrimination

Anti-trans health care discrimination refers to instances in which medical systems fail to recognize and provide adequate, timely, accessible, and affirming care to trans patients because of their gender identity. These instances occur in the context of policies and practices rooted in cisnormativity, both inside and beyond the health care sector. *Cisnormativity* can be defined as the hegemonic assumption that only cisgender people are normal, and those who are not cisgender are abnormal.

This entry first explores how cisnormativity has been structured into medical systems, facilitating anti-trans health care discrimination at systemic, institutional, and interpersonal levels. It then discusses the consequences of this discrimination on individual and population health. Finally, it concludes with recommendations for preventing and addressing anti-trans health care discrimination by challenging cisnormativity in multiple contexts.

Structural Cisnormativity in Medical Systems

Understanding anti-trans health care discrimination requires analysis of how Western notions of medicine and gender have been co-constructed throughout history. In brief, Western medicine is built to serve cisgender (cis) bodies and is specifically predicated on the notion that cis men are the standard biological human form to which all others are simultaneously derivative and inferior. This belief positions trans people as inherently "abnormal" or "deviant" and both medicalizes and erases trans people's identities, behaviors, and experiences.

Western medicine and other health sciences have long been concerned with how cis women differ from cis men. This began as early as the ancient Greek philosopher Aristotle, who claimed that (cis) women can be best understood as impotent (cis) men. A more modern manifestation of this phenomenon is the U.S. Food and Drug Administration and National Institutes of Health's combined efforts, beginning in 1993, to work toward equal representation of cis men and women in clinical trial research. While this effort resulted in improvements in the field's understanding of cis women's health, trans people remain absent from most clinical trial research. Consequently, use of the gender binary (i.e., that cis men and cis women are exhaustive gender categories) as an organizing

concept for research has resulted in a dearth of information about trans people's health. For example, current health information guidelines about symptoms and treatment recommendations of many conditions, including heart attacks, stroke, certain cancers, and autism, suggest that these conditions manifest differently in (presumably cis) men and women, yet information about trans people's experiences is typically absent.

While certain aspects of trans people's health are therefore completely overlooked as a result of cisnormativity in health care systems, other aspects are inappropriately pathologized. Pathologization of trans identity became a defining feature of trans health care in the mid-20th century when advancements in gender confirmation surgery and hormone therapy forced trans people who sought these procedures to describe their experiences as a mental illness, physical malady, or other sickness in order to receive a diagnosis of "transsexualism" and access medical gender affirmation. This phenomenon has led historians and feminist scholars to erroneously claim that trans people did not exist before the advent of successful gender affirmation surgeries, inextricably linking trans existence to medical gender affirmation. In actuality, there are documented accounts of trans people who did and did not participate in what is now termed *medical gender affirmation* since ancient times.

In the 21st century, health care systems continue to rely on this "medical model" of trans identity when determining access to medical gender affirmation. Providers frequently diagnose trans people seeking medical gender affirmation with "gender dysphoria" in order to obtain insurance authorization for hormone treatments, surgeries, and other procedures. *Gender dysphoria* refers to the distress trans people may feel due to a mismatch between their gender identity and sex assigned at birth. Psychiatrists adopted this term as a less stigmatizing alternative to *gender identity disorder;* however, not all trans people who desire medical gender affirmation experience gender dysphoria. The focus on gender dysphoria rather than the enjoyment or satisfaction derived from concordances between their gender identity and gendered features associated with a gender other than that associated with their sex assigned at birth (sometimes termed *gender euphoria*) continues to force trans people into a medicalized illness framework reliant on the gender binary.

Consequently, when trans people enter the health care system in pursuit of medical gender affirmation or many other primary care services (i.e., what cis people may consider "routine" care), they encounter a system that was not designed to meet their needs and has evolved to delegitimize their existence. The following sections discuss systemic, institutional, and interpersonal manifestations of anti-trans health care discrimination that result from this structural cisnormativity.

Manifestations of Anti-Trans Health Care Discrimination

Systemic Anti-Trans Health Care Discrimination

Norms, regulations, and policies that exist in the health care system and adjacent systems such as education, law, and social services create conditions that allow for systemic anti-trans health care discrimination. These societal features are rooted in cisnormativity and shape trans people's experiences with health care regardless of individuals' social positioning or the practices that exist in any particular health care setting.

For example, when electronic heath records (EHRs) and vital records systems began to collect information on gender, the options available for birth certificates, medical intake forms, and census forms reflected the gender binary: male and female. These systems have since been updated in certain locations, such as Oregon's 2016 allowance of X in place of M or F on driver's licenses, and certain institutions, such as the Health Resources and Services Administration (HRSA), have funded health centers' mandated collection of gender identity data. However, collecting robust data on patients' sex and gender identity is not yet universal practice. Failing to adequately capture this information exposes trans people to discrimination as it allows insurers to deny coverage for procedures deemed "sex specific" (i.e., mammograms, hysterectomies). Trans people who have changed their gender marker (i.e., M, F, X)

on some but not all forms of legal identification have also been denied health insurance coverage completely because EHR systems have been unable to process their data. Most medical records technicians have not been adequately trained in updating and maintaining EHRs for trans patients or interacting with insurance providers on their behalf.

Insurance providers also enact systemic anti-trans health care discrimination by denying coverage for medical gender affirmation. Although an increasing proportion of policies do cover these procedures, there are widely variable legal protections for trans people seeking coverage that reduce access. For example, as of 2020, 30 U.S. states do not have laws providing any LGBTQ-inclusive insurance protections, and only 24 states explicitly prohibit insurance providers from refusing to cover gender-affirming procedures in their policies. Trans people in states that do not protect them against these exclusions may be denied coverage on the grounds that medical gender affirmation procedures are "cosmetic" or "experimental." Although Medicare began covering medical gender affirmation nationwide in 2014, Medicaid has not followed suit. As of 2020, 10 states prohibit trans Medicaid beneficiaries from accessing coverage for medical gender affirmation, and an additional 18 states have no explicit Medicaid policies covering medical gender affirmation. Importantly, even in places where adequate legal protections do exist, trans people are still denied access to this medically necessary care through systemic employment discrimination, prohibitively high copays and deductibles, and preauthorization requirements.

The systematization of anti-trans health care discrimination is further evident in the education health care providers receive, including in medical schools. Health care providers, including nurses, doctors, and mental health professionals, report receiving little training on delivering gender-affirming, trans-inclusive care. In many programs, trainees must elect to attend LGBTQ health webinars or supplemental sessions to receive any training in treating trans patients. In other programs, caring for trans patients may be covered only in brief yet mandatory sessions on LGBTQ health. Neither of these models devote adequate time to the unique and specific needs of trans patients. As a result, providers report feeling inadequately prepared to care for trans patients and feeling discomfort while interacting with trans patients. Many primary care providers learn, for example, that only specialists such as endocrinologists can provide hormone therapy to trans patients, yet they will typically provide hormone therapy to cis patients without specialty consultations.

Interpersonal Anti-Trans Health Care Discrimination

Interpersonal anti-trans health care discrimination occurs whenever individual providers or health care administrators treat trans patients inequitably on account of their gender identity. It is important to recognize that each individual instance of this sort of discrimination occurs in the context of laws, policies, and norms designed to reduce trans people's access to adequate health care and a medical system structured around cisnormative beliefs. Trans people have long reported high rates of denial of care. Individual accounts have attributed these experiences to a provider's or institution's religious beliefs, such as when a Catholic hospital canceled Evan Minton's scheduled surgery in 2016 only after learning he identifies as trans. However, other instances of denial of care have not been connected to religious beliefs, including the 1995 death of Tyra Hunter, a Black trans woman who died after EMTs referred to her with anti-trans slurs and refused to care for her treatable injuries sustained in a car accident.

In addition to denial of care, trans patients have reported high rates of physical assault, harassment, and verbal abuse in health care settings. This includes being openly mocked, ridiculed, and derided by health care staff or other patients in public waiting rooms or communal treatment settings such as emergency rooms; having private health information inappropriately shared among staff; and being misgendered and misnamed (i.e., referred to by an incorrect name or gender pronoun) while in care. In some cases, providers justify anti-trans health care discrimination and mistreatment using the medical model of trans

identity. For example, trans people have reported health care providers refusing to prescribe hormones unless they are allowed to perform a pelvic exam, which is not medically indicated for hormone replacement therapy.

Interpersonal anti-trans health care discrimination may also manifest as the provision of inadequate or deliberately harmful care. Trans people have used the term *trans broken arm syndrome* to refer to how health care providers tend to attribute any injury or illness to a patient's trans status no matter how irrelevant. Trans people who experience such treatment may be forced to delay receipt of needed care or be subject to unnecessary, invasive, and dehumanizing questioning, medical exams, or procedures. This phenomenon is especially common in mental health care settings, where symptoms of conditions such as bipolar disorder, anxiety, and posttraumatic stress disorder may be attributed to, or conflated with, a patient's trans identity. A growing number of "gender critical" therapists, counselors, and psychologists now promote the idea that trans-identified or otherwise gender-expansive children, adolescents, and young adults will "desist" wanting to transition if provided appropriate psychological care. This "wait-and-see" practice, which lacks an adequate evidence base, jeopardizes trans youths' health and safety by delaying their access to gender affirmation.

Consequences of Anti-Trans Health Care Discrimination

The extent to which anti-trans health care discrimination results in adverse health consequences for trans patients is not well studied, owing to lack of longitudinal data that can directly isolate and establish causality regarding the impact of multiple forms of discrimination on health outcomes. Preliminary research, however, has documented some ways in which discrimination may reduce trans people's access to needed care, cause trans patients to avoid needed care, and directly affect their health.

Access to Care

Systemic and interpersonal anti-trans health care discrimination reduces trans people's access to care by limiting their access to health insurance; medical care, including medical gender affirmation; and mental health care. Despite efforts of the 2016 Affordable Care Act to extend trans-inclusive health insurance coverage to all people in the U.S., trans adults continued to be insured at lower rates than cis adults. This disparity is a consequence of inequitable economic opportunities for trans people, who are less likely than cis people to be employed in full-time positions that provide benefits such as health insurance. Furthermore, trans people may not perceive the cost of health insurance as worth the benefits, because available programs may not adequately cover gender-affirming care such as hormones, surgeries, and mental health care.

As a result of both lower rates of insurance enrollment and care avoidance, trans people may be less likely than cis people to receive routine primary health care. As of 2020, there are few studies examining specific routine care procedures such as flu shots or checkups among trans populations. However, trans people are less likely to receive lung cancer screenings than cis people despite similar smoking behaviors, suggesting that trans people may have reduced access to needed preventive care. Trans people are also more likely than cis people to report that cost is a barrier to care and less likely than cis people to have a primary care provider.

In addition to preventive care, anti-trans health care discrimination also directly reduces access to medical gender affirmation. While the World Professional Association for Transgender Health (WPATH) has attempted since 2011 to depathologize trans people by promoting an informed consent model to providing medical gender affirmation, medical, mental health care, and social service providers still act as gatekeepers to medical gender affirmation by deciding who is and is not a "legitimate" trans person. Such discriminatory behaviors reduce access to medically necessary care, particularly for nonbinary and gender-nonconforming trans people, trans youth, low-income trans people, and trans people with disabilities. Even under an informed consent model, providers may require patients to attend several appointments before providing treatment such as hormone therapy, creating additional opportunity costs and barriers to care. This especially affects trans people living in rural areas who have reported traveling long distances to find a provider willing to prescribe

hormones for gender affirmation. These providers are less likely to be in their insurance networks, creating additional financial barriers to care.

Additionally, anti-trans health care discrimination reduces access to mental health care. In the absence of standards or requirements for mental health professionals regarding inclusive care of trans patients, trans people must identify trans-affirming providers from the array of providers available to them on their own. In major metro areas, LGBTQ health care organizations have sought to directly connect trans patients seeking mental health care to vetted providers. However, the services these programs offer are typically short term and may not adequately address all patients' mental health care needs. As with medical gender affirmation, trans people living outside of major metro areas are likely to report more difficulty with finding trans-inclusive mental health care in their communities than do those who have access to urban LGBTQ health centers.

Care Avoidance

As a consequence of systematic and interpersonal anti-trans health care discrimination, trans people are likely to view health care spaces as inherently stigmatizing. Trans people tend to anticipate discrimination in situations where their gender identity may be both perceptible and salient. This includes health care encounters in which, because of how medical science, patient data collection, and patient–provider interactions have been structured, disclosing one's gender identity may be necessary to receive adequate care. For example, trans people are more likely to decline or avoid procedures that may make their gender identity more salient in a health care setting, such as mammograms and cervical cancer screenings, as compared with other routine procedures.

Because of the high degree to which trans people anticipate discrimination in medical encounters, trans people are likely to postpone or completely avoid seeking needed care. Care avoidance is more prevalent among trans people who have encountered interpersonal anti-trans discrimination in a health care setting than those who have not, suggesting that care avoidance may frequently result from personal experience. In particular, large-scale studies have shown that trans patients who have had to teach their providers about trans health care are more likely to delay care than those who have not, indicating that inadequate provider training in delivering trans-inclusive care may be causing care avoidance.

In studies of cisgender populations, avoiding routine care for any reason is associated with greater use of emergency rooms for preventable health emergencies. This would suggest that trans people likely use emergency rooms at higher rates than do cis people; however, studies have shown that trans people are extremely hesitant to visit emergency rooms during health crises as well. This may be because emergency rooms do not allow for patients to select their providers, limiting trans people's abilities to choose a trans-competent provider who is in their insurance network. Among trans populations, care avoidance has been associated with suicidality, substance use, and depression, which makes emergency room avoidance a troubling phenomenon, given that trans people who avoid care may be more likely to experience psychiatric emergencies.

Health Outcomes

While it is difficult to investigate the total impact of anti-trans health care discrimination on the health of trans populations, existing studies indicate that direct experiences with interpersonal anti-trans health care discrimination are associated with poor mental health outcomes. In particular, trans patients who have experienced denial of care and provision of inadequate care are more likely to have depression, suicidal ideation, and psychological distress than do trans patients who have not faced these forms of discrimination. Given the overall high burden of mental health issues among trans populations, it is especially concerning that seeking health care may exacerbate these issues.

The consequences of lack of access to transition-related care are better understood. In both children and adults, being denied access to desired treatments such as hormones and surgeries has been linked to psychological distress, depression, and suicidal behavior. To avoid these consequences, trans people who cannot access or choose to avoid health care may find alternate pathways to meet their gender affirmation goals. These may include the use of non-prescribed

hormones accessed online, through friends, or through other nonmedical channels. While the medical consequences of nonprescribed hormone use in relation to prescribed hormone use are not well documented, hormone replacement therapy has the potential to cause iatrogenic effects such as deep vein thrombosis, pulmonary embolisms, and problems with liver or kidney function that could be extremely harmful or even fatal if not monitored and treated by a medical professional. Aside from hormone use, trans people may use other methods to modify their appearance in accordance with their gender identity. These include common practices such as long-term breast binding—which may cause broken ribs, create respiratory distress, and exacerbate asthma—as well as less common practices such as self-surgery.

Recommendations

Table 1 presents recommendations for how to prevent and address anti-trans health discrimination at multiple levels. Objectives at the structural, systemic, institutional, and interpersonal levels of the health care system are identified to guide overall efforts at reducing anti-trans health discrimination as well as potential steps that serve as examples of ways to work toward each objective.

Table 1 Recommendations for Addressing Anti-Trans Health Discrimination

Level	*Objective*	*Potential Steps*
Structural	Reorganize health care practices away from the gender binary and fallacy of biological sex	• Revise medical guidelines based in the gender binary • Prohibit genital mutilation of intersex infants • Study the impacts of drugs, surgeries, therapeutic approaches, and other treatments with trans samples
Systemic	Enact macro-level reforms that support widespread provision of gender-affirming care and provide trans people recourse for experienced discrimination	• Train generalist providers such as nurse practitioners, pediatricians, and primary care physicians in provision of hormone therapy for transgender patients • Enact legislation requiring private and public insurance programs to cover medical gender affirmation care • Establish accessible channels for trans patients to report health care discrimination to local, state, and federal authorities
Institutional	Incorporate best practices in trans-affirming care in all health care settings	• Hire case managers to assist transgender patients in navigating insurance processes, exploring legal gender affirmation processes, and accessing gender-affirming medical and mental health care as needed • Provide patients, families, and staff access to all-gender restrooms and changing rooms • Collect patient data on sex assigned at birth and gender identity and analyze trends in patient retention and outcomes
Interpersonal	Reduce perpetuation of anti-trans stigma in clinical encounters	• Create feedback systems for trans patients to convey their satisfaction with providers and, when necessary, request new ones • Design protocols for reengaging trans patients who may be avoiding or delaying care • Prioritize hiring of trans-identified health care providers and staff

Health Care Access, Legal Issues

Access to health care is a critical issue for many trans people. Yet, barriers abound, and discrimination continues to be a major problem. This entry details examples of legal issues related to trans health care access over time, including access to transition-related and general health care and discrimination based on trans identity. In the sections that follow, legal issues for various health care programs and policies are discussed, including the Affordable Care Act, Medicaid, Medicare, and health care for incarcerated people. In addition, the entry provides information about related documentation barriers as well as intersectional considerations with health care access.

History of Trans Health Care Access and Legal Issues

Trans people's access to health care across history has been rife with stigma and barriers, including the pathologization of gender diversity in medicine. Throughout the 20th century, myriad medical treatments were tried (and failed) to "cure" gender nonconformity, including prefrontal lobotomy, electric shock therapy, reparative therapy, and pharmaceuticals. Viewing trans identities akin to an "infectious disease" is now commonly acknowledged by medical professionals as inappropriate, ineffective, and harmful to patients. Nonetheless, there are continued efforts to promote harmful, unproven practices, such as reparative therapy for youth, which is still the subject of proposed legislation in some U.S. states as of early 2021.

Transition-related care, including hormone therapy and transition-related surgeries (e.g., breast augmentation, hysterectomy, vaginoplasty, orchidectomy), has developed over time and been supported by a variety of medical professionals as

being important for trans individuals. Magnus Hirschfeld of Germany (1868–1935) was one of the first doctors who surgically altered patients' genitalia. By the early 1920s, some doctors in the United States were carrying out castrations or hysterectomies for patients desiring to live as another gender, and endocrinologist Harry Benjamin was administering hormone therapy to patients as early as the 1930s. For the next 20 years, only a few American doctors were known to perform sex reassignment surgery on patients who were not intersex. Benjamin helped trans patients connect with surgeons who would perform genital plastic surgery, although this was difficult at the time, as multiple U.S. states as well as European countries banned such surgeries. In 1949, Edmund Brown, the attorney general of California, issued a decision that genital surgeries contributed to "mayhem" by harming healthy tissue, arguing that such procedures should be illegal. This ruling also contributed to the difficulties of making genital surgeries more widely available. Thus, some of Benjamin's work supporting trans patients had to be conducted clandestinely.

Throughout this history, cisgender (those who are not trans; cis) scientists and medical providers were generally the ones controlling the types of health care that trans patients could access. In the mid-20th century, cis psychiatrists were still often critical of gender-affirming surgeries and believed that transsexual individuals had a mental disorder that could not be addressed through surgery. Physicians educated on genital plastic surgeries regularly denied trans people access. By 1979, a group of researchers, physicians, and therapists developed the Harry Benjamin International Gender Dysphoria Association, now called the World Professional Association for Transgender Health (WPATH). During the 1980s, WPATH played a role in challenging legal barriers and discrimination affecting trans patients who wished to transition, such as local laws requiring transitioning individuals to be sterilized or to divorce their spouses.

With the emergence of the HIV/AIDS epidemic in the 1980s and 1990s, trans people were greatly affected and subjected to a systemic lack of attention by medical professionals and government. Trans individuals living with HIV were among those engaged in activist groups such as ACT-UP, Queer Nation, and Transgender Nation that drew attention to HIV/AIDS and the need for interventions. There are numerous other examples of trans activists pushing for changes to legal issues related to health care. For example, in 1986, Louis Sullivan, a gay trans man, created FTM International and lobbied the American Psychiatric Association and WPATH to eliminate sexual orientation (being heterosexual) as a qualifier for supporting gender transition.

WPATH played a role in challenging the use of pathologizing diagnostic codes for trans people to access transition-related health care. When gender identity disorder was added as a diagnosis to the third edition of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*) in 1980 (a publication of the American Psychiatric Association that classifies mental health disorders), it was based on a stigmatizing understanding of trans identities stemming from Freudian and Eriksonian psychodynamic theories. The most recent versions of the *DSM* (*DSM-5*), WPATH Standards of Care (Version 7), and *International Classification of Diseases* all use categorizations and medical codes that are intended to be nonpathological means for indicating the need for transition-related care. WPATH identified the phrase "gender dysphoria" to describe the distress caused by a mismatch between gender identity, gender expectations, and sex assigned at birth and identified criteria through which this condition could be diagnosed and medical treatments offered to contribute to a therapeutic process. Yet, this diagnostic code often means that access to gender-affirming treatment hinges upon the gatekeeping of medical professionals, particularly (cis) mental health professionals. Some trans leaders and medical professionals advocate for the use of an informed consent model, which prioritizes the patient's ability to fully understand the ramifications of and consent to gender-affirming treatments rather than relying on the mental health provider to give permission after an assessment for readiness to transition.

Transition-Related Care

For trans people, having access to transition-related health care is imperative. While not all

trans people choose to access transition-related care, many trans people need such care and would argue that this care is lifesaving. This care can include hormone replacement therapy (HRT), gender-affirming surgeries and procedures, mental health care, and sexual and reproductive health care.

In the United States, as of the beginning of 2021, 24 states and Washington, D.C., prohibit health insurance plans from denying health care because it is trans related. Federal law and some state laws prohibit many public and private health plans from discriminating against a person because they are trans, including refusal to cover medically necessary transition-related care. The caveat to this is that it is unclear what most health insurance companies deem as "medically necessary."

Gatekeeping

According to the WPATH Standards of Care, it is recommended that a trans person receive a letter, or multiple letters, from a mental health provider to access transition-related care. Unless a medical provider operates under an informed consent model, many health care organizations and university hospitals require a letter from a mental health provider to schedule various gender-affirming surgeries or to prescribe hormones. If a mental health provider has an issue with a trans person accessing care or does not support someone who is transitioning, they may decline to write a letter, resulting in the trans person's having to find a different provider. This is a barrier for trans people who need a life-changing or even lifesaving procedure and can be referred to as *gatekeeping*. Gatekeeping is when someone in a position of power decides who does or does not have access to something. Gatekeeping particularly affects the lives of trans people who hold multiple marginalized identities, such as being Black or brown, poor, or having a disability.

Negative Experiences With Health Insurance

According to the 2015 United States Transgender Survey (USTS), which surveyed over 27,000 trans adults, 55% of respondents who submitted a request to their insurance company were denied coverage for a transition-related surgery, and 25% were denied coverage for transition-related hormone therapy. Another issue trans people often face with insurance companies is a refusal to update or change legal documentation. The USTS found that 17% of trans people had an insurer refuse to change their name and/or gender marker in their insurance record. This can result in a denial for transition-related coverage due to gender not aligning with the procedure or service requested. An example of this is that if a trans man needs testosterone for HRT, the insurance may deny the request if the insurance record states that the patient's sex is female.

Denying Health Care to Trans Youth

In 2020, legislators in 10 states introduced bills that would criminalize lifesaving medical care for trans youth. These bills focus on hormone replacement therapy or, in some cases, all transition-related care, insisting that trans youth are too young and incapable of making a decision that will affect them long term. Should any of these bills pass, medical providers could lose their state license or face criminal charges for providing transition-related care to youth, even with parental consent.

Current Legal Issues With General Health Care

Beyond transition-related care, trans people need access to other health services, from primary care and emergency care to specialists, prescription medications, and nursing homes. Since the early 2000s, legal protections to ensure such access have expanded, although there remains a frequently changing patchwork that depends on the priorities of presidential administrations and legislative bodies. The 2010 Affordable Care Act (ACA) made it illegal for most health providers and organizations to discriminate against trans people. Such protections extend to doctors' offices, health clinics, rape crisis services, nursing homes, and home health providers, among other settings. Through the ACA, trans patients should not be treated differently than other patients,

should not be refused care or charged more, and should not be forced to undergo unnecessary examinations or reparative therapy. Furthermore, trans patients should be able to access care and services that match their gender identity. Nonetheless, trans people continued to regularly experience mistreatment in the medical system after the ACA's implementation.

In 2020, the Trump administration ordered rule changes to the ACA that removed prohibitions against discrimination based on gender identity and sexual orientation. But these changes were reversed by the Biden administration, based on the Supreme Court having ruled in 2020 that the prohibition against sex discrimination in employment in Title VII of the Civil Rights Act of 1964 includes discrimination based on gender identity and sexual orientation. The decision set a precedent for trans people being covered under laws banning sex discrimination in other areas, including health care. Indeed, a district court in Minnesota ruled in 2015 that the ban on sex discrimination in the ACA includes discrimination based on gender identity.

Discrimination in Health Care Services

Many medical schools still provide little if any information about effectively serving trans patients, and providers who espouse transphobic beliefs may feel little impetus to treat trans patients in an affirming and equitable manner without legislative or institutional policies in place. Some entities have initiated their own policies; for example, the Joint Commission Hospital Accreditation Standards prohibit discrimination against trans patients.

Numerous legal cases have addressed the issue of trans discrimination in general health care. The 2016 case *Prescott v. Rady Children's Hospital* focused on a 14-year-old trans boy, Kyler Prescott, who was admitted to a hospital for self-injurious behavior and suicidal ideation after experiencing trans harassment from other youth. Hospital staff continued to refer to Kyler as a girl and use she/her pronouns, even after Kyler's mother repeatedly corrected them, subjecting him to additional trauma. Kyler was released before the recommended 72-hour period and died by suicide several weeks later. This case was eventually settled with the family but is one indication of how transphobic treatment in mental health care can affect trans patients.

Discrimination in Insurance Coverage

Despite most public and private health insurance plans banning discriminatory practices, insurance discrimination against trans people is not uncommon. In the 2015 USTS, 13% had been denied coverage for services often associated with one gender such as mammograms, and 7% were denied coverage for other routine care.

Disclosure of Protected Health Information

The Health Insurance Portability and Accountability Act (HIPAA) protects the privacy of patients' health and medical records and applies to most health care providers and insurance programs. Protected information includes one's identity as trans as well as one's medical history, diagnoses, anatomy, and sex assigned at birth. Such information is not to be shared without the patient's consent—including with family members—and should only be disclosed to other medical staff when necessary. Yet, research and legal cases have documented numerous instances of providers who illegally disclose information about trans patients, such as gossiping about a patient's anatomy or telling family members that the patient is questioning their gender. Such occurrences can be a violation of HIPAA.

Legal Issues With Providers

Discrimination by Medical Providers

A 2019 study in the midwestern United States indicated that increasing providers' education about trans health may not improve their sensitivity in serving trans patients. This study suggests that the underlying issue is transphobia and that addressing transphobia in medical education is needed to help providers effectively serve trans patients. According to the USTS, 23% of trans people avoided seeking necessary health care for at least 1 year, owing to the fear

of being mistreated. In addition to this, trans patients are often placed in educator roles, being expected to teach a provider about trans people. As a result of such situations, trans people are four times more likely to delay needed health care.

Legal Issues With Health Care Programs and Insurance Coverage

The ACA is not the only health care program that affects trans people. Many trans people have served in the U.S. military, and data suggest they may be more likely to serve than the general population—even though trans people were only allowed to openly serve in the military from 2016–2017, when the Obama administration rescinded the trans military ban, and then again in 2021, when the Biden administration lifted the ban reimposed by the Trump administration. Many trans people receive health care through various programs associated with the military, including the Veterans Health Administration (VHA), TRICARE (for active duty service members), and the CHAMPVA program for certain dependents of veterans. The Veterans Administration (VA) has policies in place to prohibit discrimination for trans patients and for ensuring patients are treated according to their gender identity and medical information is kept confidential. Although veterans' health programs cover mental health care, medically necessary prosthetics (such as dilators and binders), pre- and postoperative care, and hormones related to transitioning, there continues to be a lack of insurance coverage by the VHA, TRICARE, and CHAMPVA for gender-affirming surgeries, which has been the subject of numerous lawsuits. This exclusion continues despite estimations by the RAND Corporation that transition-related health care would constitute an "extremely small" number of cases of active duty service members.

Medicaid policies related to trans patients vary by state according to their interpretations of the federal government's regulations for this program. As of early 2021, 22 states, Washington, D.C., and Puerto Rico cover transition-related care under Medicaid; 18 states have no policy regarding coverage; and 10 states exclude transition-related care in Medicaid.

Medicare covers medically necessary hormone therapy and gender-affirming surgeries, as well as preventive care (including prostate exams, mammograms, etc.), even when there may be a gender mismatch on medical/billing documents. Private Medicare plans also cover prescription drugs related to hormone therapy. Beneficiary cards for Medicare Parts A and B no longer indicate gender, so one's records are usually tied to Social Security data (which can be updated); regardless, one's gender on these records should not affect Medicare coverage. Like coverage for other services through Medicare, transition-related care is evaluated on a case-by-case basis. Certain Medicare contractors and Medicare Advantage plans have their own precise policies for coverage of transition-related care that affect decisions about what care will be covered. The National Center for Transgender Equality encourages trans patients who have a Medicare Advantage plan to seek preauthorization for transition-related care before attempting to access these services. Trans patients sometimes experience denial of coverage for transition-related services as well as other needed care, and in such cases, they are encouraged by advocates to talk with a lawyer and consider filing an appeal to Medicare.

There continues to be a lack of clarity from Medicare about how providers should bill for gender-affirming surgeries, which can create barriers for trans patients. Medicare does not approve payments until after a surgery is completed. This lack of clarity has led some private providers not to accept Medicare as a form of coverage for transition-related care. Thus, many of the gender-affirming surgeries that are performed under Medicare occur at university medical centers because they cannot opt out of Medicare coverage.

When Medicare billing procedures are unclear, doctors may become confused about which billing codes to use and run the risk of not being paid or placing the financial costs on the shoulders of patients. A disproportionate number of trans patients already face significant financial barriers for medical care, as they may live in

poverty, be homeless, and/or not be employed outside of the home. Furthermore, while Medicare beneficiaries among the general population are most often aged 65 or older, a 2016 report from the Centers for Medicare & Medicaid Services indicated that 77% of trans beneficiaries were younger than age 65, and 85% of all trans beneficiaries accessed Medicare through disability insurance.

Private health insurance plans have varying policies regarding covering trans patients. As of early 2021, 24 states and Washington, D.C. had laws stating that private insurance plans could not exclude trans patients from services.

Several legal cases have argued that trans prisoners should be treated equitably in health care and have access to transition-related care. All seven of the U.S. circuit courts have noted that gender dysphoria is a serious medical condition, and several courts have recently found that denying medically necessary care for gender dysphoria to prisoners constitutes cruel and unusual punishment. In the case *Adams v. Bureau of Prisons*, the Bureau reversed an earlier rule that kept trans prisoners from using transition-related care unless they had accessed such care before entering prison. In December 2018, a federal district court decided in favor of a trans woman in Idaho accessing medical care for gender dysphoria. In August 2019, the 9th U.S. Circuit Court of Appeals upheld this ruling, stating that not providing adequate health care to trans prisoners is cruel and unusual punishment.

Documentation

Trans people often need to update their legal documents to reflect their correct name and gender. To change the name listed on a federal or state identification (ID) card, the first step is typically receiving a legal name change from a court. This process varies by state, with some states requiring name changes to be published in a newspaper before a court will grant the name change. To update a gender marker, most states require some form of documentation from a health provider to confirm that a person is transitioning. This must be a provider who has completed a gender-affirming procedure or prescribed or continued HRT. This also varies in each state, and some states will not permit gender marker changes on some forms of documentation, such as birth certificates. Depending on the state, a trans person may have a different gender marker on their state ID card than what is on their birth certificate.

Because of the emotional and financial hardship that may come with updating legal documentation, many trans people do not update their documents. According to the 2015 USTS, 68% of respondents did not have their correct name and gender marker on their legal documents. This likely creates barriers for trans people accessing care because they must present documents in a way that feels inauthentic. This also could result in trans patients being called their former names or being misgendered by medical clinic staff.

An Intersectional Perspective on Legal Issues in Health Care

Trans people's experiences of health care and related legal issues are affected by the myriad identities they hold and forms of marginalization that affect their lives, above and beyond their status as trans. Black trans women are disproportionately harmed by social systems in the United States. Black trans women are more likely to be murdered, experience violence, and experience police brutality than other trans people. More broadly, people of color are more likely to experience health care discrimination than their white counterparts. Race is a substantial determinant of health care discrimination, particularly for African Americans and Native Americans. In a 2015 study, trans people of color had substantially higher reports of discrimination than white trans people. In the USTS, Middle Eastern and American Indian participants were more likely to report not going to a health care provider because of fear of being mistreated due to being trans. Similar to communities of color, people with lower socioeconomic status (SES) encounter significant barriers when navigating health care systems, including struggles with paying for care out of pocket.

Most research focused on the trans community is binary, with a lack of research on nonbinary identities. Owing to the lack of research, health

care providers are not likely well informed about nonbinary patients and their needs. With nonbinary visibility increasing, as of early 2021, 19 states and Washington, D.C., allow people to select an "X" as the gender marker on their driver's licenses and 13 states enable adults to have an "X" on their birth certificates.

Health Care Training

Health care training encompasses the programs, curricula, and tools that are used to build competency in health care professionals. The lack of education of care providers is often cited as a barrier to competent and welcoming trans health. As such, it is important to understand the history and development of trans health education and to conceptualize the key components of trans health education. Trans health is practiced by a variety of clinicians, including primary care (e.g., internal and family medicine) and subspecialists (e.g., endocrinology, gynecology, and surgery), as well as adult and pediatric clinicians. Trans health teams are also often multidisciplinary, including front-of-house and administrative staff, clinic navigators, nurses, physicians, mental health clinicians, and allied health workers. Given the diversity of the field and backgrounds of those needing education, a one-size-fits-all model is not likely to be applicable.

Trans Health Education History

Trans people have actively engaged in advocating for trans medical service models since at least the late 1800s in Europe and the 1960s and 1970s in the United States. Prior to the existence of standardized guidelines, information about trans health was disseminated mainly between trans community members. Due to the lack of respectful and knowledgeable health care, trans people frequently feel the need to teach their clinicians about trans people in order to receive the care they require. This educational labor has traditionally been offered informally and freely in the form of, for example, patient-to-provider advice giving or trans people giving unpaid lectures at institutions.

While trans health, as well as the education of clinicians, has expanded rapidly since the turn of the 21st century, the initial educational models predate this. Most early trans health knowledge was passed down through mentorship and apprenticeship. In the early 20th century, the Institute of Sexology in Berlin, Germany, run by sexologist and physician Magnus Hirschfeld and numerous trans-identified colleagues, helped craft the foundation for the endocrinologic and surgical care of trans

people (the institute was demolished and its library burned after the Nazi Party came to power in the 1930s). In the late 20th century, trans health education began to formalize again as clinicians around the world began connecting through newly founded trans health organizations such as the World Professional Association for Transgender Health (WPATH), and trans activists and clinicians began advocating for training programs to recognize trans health as an equitable part in education. The Harry Benjamin International Gender Dysphoria Association Standards of Care (later iterations come to be known as the WPATH Standards of Care for the Health of Transsexual, Transgender, and Gender Nonconforming People), published in 1979, set forth a foundation of clinical guidelines. Although trans clinical access grew through the latter 20th and early 21st centuries, it also became apparent that the existing capacity to deliver formal education was inadequate to ensure clinicians and allied health professionals were prepared to provide consistent and culturally affirming care.

No such training exists for all fields and all levels of education; research shows a great need for educational models in all areas. A survey of students from medical, nursing, and pharmacy schools indicates that their present education does not adequately prepare them to care for trans patients. While advancements have been made in broader LGBTQIA+ curricula, students acknowledge that they are weighted more heavily toward LGB education than trans health. Furthermore, as trans health curricula are in their early development, there is a critical awareness of the void felt by those who have already completed their medical education and are thus seeking trans health continuing education.

Although numerous fields desire additional education on trans health, no uniform model can apply to all who request training. This has significantly limited the expansion of trans health education as it ultimately falls to independent institutions to deliver training that is specific to the needs of its type of trainees. Even continuing medical education curricula, which are meant to apply to more than one field, can be limited in their broad applicability across specialties and disciplines.

Approaches to Trans Health Education

Although literature is scant when it comes to assessing the best approach to trans health education in any one specific field, certain curricular themes emerge. Didactics have been shown to be beneficial in numerous educational settings for providing both foundational knowledge and advanced training for specialty-specific education. Such didactics help to ensure that people from diverse backgrounds are all working from the same conceptual basis, cultural understanding, and core values of ethics and expectations. Organizations such as the American Association of Medical Colleges (AAMC), which provides training curricula for use across programs, have recognized the value of creating didactics that can be integrated into individual programs. Research has shown that despite their relatively introductory nature, these have significantly contributed to improving the trans health knowledge base of learners.

Case studies (written vignettes of patient stories with problem-based learning questions) and standardized patients (persons who portray patients in training scenarios for clinical skills instruction) are additional teaching modalities in use for trans health education. Case-based curricula personalize the learning experience for trainees with either written patient vignettes or in-person standardized patients, with the goal of not only helping the students to understand the relationships, identities, and social disparities that affect the way a trans patient might perceive or navigate their care but also helping them practice trans-specific patient interviewing skills.

Combining these educational models has also been shown to be beneficial in trans health education. Additionally, curricula can be improved by the use of personal engagement experiences beyond the standardized patient, such as the inclusion of a patient panel of trans-identified health care workers, which allows the student to learn from and interact with persons of trans experience beyond the patient care setting. This is further enhanced when the curriculum expands beyond a single experience and is longitudinally integrated across a learner's training. This ensures that as a trainee is growing and maturing in their understanding of other areas of their field, they are also integrating their growing knowledge and understanding of trans patients' experiences and needs.

Trans Health Education Policy

Numerous organizations have supported the need for improvement in trans health education. Student

groups have been early leaders in the vocal push for improvement in trans health curriculum on their campuses, including promoting the expansion of existing minimal curricula. Numerous medical organizations have also publicly supported the needs for improvement and formalization of trans health training, including the AAMC (which has published guidelines on LGBTQIA+ health medical school curricula since 2014) and the Graduate Medical Council of the United Kingdom, which has included LGBTQIA+ competence in its core ethics. Numerous specialty medical boards have also built trans health into their competencies.

Educating the Trans Health Team

Trans health teams often reflect the grassroots origins and evolution of health care provision at a particular institution or clinic. As such, there is presently no one standard way to create a trans health team. For example, trans health advocacy organizations assert that a variety of providers, including pediatric and adult, primary care and specialty, can be trained in gender-affirming hormone therapy.

Whereas clinical knowledge of gender-affirming mental health, primary care, hormone therapy, and surgical care is integral to trans health education, clinic staff's approach and attitude are at the core of trans health training. Health care staff are charged with assessing their attitudes toward trans people and working to move toward inclusivity and integration. The following are examples of trans-inclusive actions: acknowledging elements of cisgender privilege, actively exhibiting gender-affirming behaviors (e.g., using correct pronouns and name, demonstrating fluency in the terminology used by trans people, avoiding unnecessary invasive questions), advocating for trans patients, and centering the voices of trans people in conversations about trans health.

The Health Care Setting

Given the frequency of negative experiences of trans patients in health care, it is essential that health care facilities foster environments that are trans affirming, at each step of the patient visit. There are numerous available guides and pamphlets that put forward best practices for creating a welcoming and safe clinical environment. Trans representation is critical to optimizing patient experiences. Clinics should consider proactive hiring practices that allow patients to feel represented in the clinicians and staff who are serving them. There are agencies and individuals that offer trans inclusivity training for frontline and support staff. Clinic administration may also choose to use a consultant to do a walk-through assessment for trans inclusivity and help to develop an improvement plan.

Additionally, given the previously mentioned informal and free educational labor offered regularly by trans people (e.g., unpaid lectures at institutions), there is a need in any initiative to improve upon or educate regarding trans health to ensure compensation is provided for the sharing of this valued knowledge and lived experience, especially given that trans people face significantly higher rates of unemployment and poverty than the general population. Opportunities for paid, experience-informed educational positions include but are not limited to community-based peer advocate and navigator positions, standardized patients, and advisory board members.

Electronic Medical Records

In addition to the face-to-face medical encounter, accurate and appropriate documentation of the visit in the electronic medical record (EMR) is needed. There is a need for the improvement of EMR systems, so that they may appropriately capture gender-related information. Health care staff must be trained on correct entry of patient information, pronouns, and gender marker. As EMR interfaces may be built with a cisgender-normative bias, staff should be trained on EMR entry and documentation "workarounds" to use while systems that are more trans inclusive are being developed.

Credentialing and Continuing Education for Primary Care Providers

As of early 2020, there is no single recognized credentialing body for the practice of trans medicine, and most employers do not require it for clinicians (including physicians, nurses, mental health

providers, or allied health professionals) to see trans patients. However, for those who chose to do so beyond their standard specialty-specific training, WPATH offers a robust certification program with continuing education requirements, including a core curriculum and additional electives, as well as required trans community listening sessions and a period of mentoring. At the same time, there also exist some smaller certification programs, owned and operated by mental health therapists and not linked to international medical associations.

Health care providers should participate in continuing education to both establish baseline competency and stay updated on the current evidence and consensus in the field. There are trans health conferences that take place globally, some of which are open to both care providers and trans community members who are seeking information about gender transition and wellness. WPATH's Global Education Initiative training courses teach providers the WPATH Standards of Care and their implementation in practice. Providers may access online opportunities for continuing education, including webinars and teleconferencing. For example, Trans ECHO (Extension for Community Healthcare Outcomes) provide online workshops that take place over a series of months with clinicians from diverse backgrounds who participate in case-based learning with peers and experts in the field. Health care facilities may also choose to engage in on-the-job-training, to ensure all clinic staff are adequately trained; this approach has been shown to improve provider confidence in the provision of trans health care.

As of early 2020, postgraduate specialty training programs for those who have completed their degrees and are interested in formal trans health education are in their nascence, with only a handful existing internationally, but are urgently needed in trans medicine, epidemiology, and public health (e.g., residency programs, postdocs, graduate student mentors).

Education of Surgeons Performing Gender-Affirming Surgeries

While there are well-established standards for training and outcomes of cosmetic, urologic, and gynecologic surgeries, there are few formal training educational programs for surgeons or surgery residents interested in performing gender-affirming surgeries; as of early 2020, there are five such programs in the United States. In addition, it is unlikely that one format of training would suit all professionals in every medical system in every culture around the globe.

In 2018, a group of trans activists who had undergone gender-affirming genital surgeries organized and called for the creation of minimum acceptable practices for surgeons performing these surgeries. This was the response to surgeons who engage in unethical or medically unsafe practices (e.g., reporting of inaccurate and incomplete complication rates, providing insufficient aftercare, counseling with inaccurate medical information). The open letter stresses the need for readiness demonstrated by an accreditation system that is developed by a medical association alongside input from the community advisory board, postoperative data collection, patient-reported outcomes, and ethical standards.

Ongoing Evaluation to Inform Training

There is a need to measure the impact and effectiveness of interventions enacted to improve trans health care. Scales have been created to measure both trans-inclusive behaviors as well as transphobia and prejudice against trans people. Comprehensive patient satisfaction surveys are important feedback tools and may be distributed regularly. Patient advisory boards comprising trans patients should be assembled in order to gather feedback on patient experience at a given facility. Trans community advisory boards of non-patients may also be created. All clinics should collect and examine trans patient complaints.

Health Determinants

Because trans populations have often been unaccounted for in major studies of general populations, health determinants and health-promoting factors among this group are a relatively understudied topic. However, as more researchers include trans populations in data collection efforts around the world, a developing body of research on social, medical, and psychological factors is relevant to the health of trans individuals, communities, and populations.

Trans identities vary widely, and it is important to consider this diversity when discussing the various health determinants and health-promoting factors that come to mind when discussing trans populations. Trans identities can vary quite significantly across regional and national cultural and legal contexts, and this can in turn shape the health patterns observed within each particular region. Intersectional factors like social class, racial and ethnic background, geographic location, immigration status, and family composition can also shape significant within-group differences in the salience of particular health determinants, risk factors, and health-promoting factors.

Health Impacts of Stigma and Social Marginalization

Many trans individuals experience pervasive social stigma and structural marginalization on a routine basis, which can have corrosive effects on physical and mental health. While there are few established causal links between particular forms of stigma and marginalization and trans health, there are some well-established associations between trans identities and particular stressors, obstacles to health care access, and increased vulnerability to poor physical and mental health.

Membership in a small or marginalized population can be linked to physical and psychological health burdens. This phenomenon, known as *minority stress,* has been identified as affecting the health of sexual minorities and marginalized racial/ethnic groups. Because trans populations are both small and structurally marginalized, the minority stress model has proven relevant to understanding certain health disadvantages that trans individuals and populations may face. Although generalizable research on trans mental health and related risk factors is relatively sparse, there is evidence that trans populations face high rates of depression and other mental health challenges. Some members of the trans population may have multiple axes of marginalization through which they experience minority stress, such as also belonging to a marginalized sexual orientation identity group, which can compound the impacts on physical and mental health.

As part of this marginalization and stigma, people, particularly trans women, may face heightened risks of violent victimization, incarceration, and sexual assault. Such experiences can result in worse physical and mental health, including but

not limited to the long-term effects of physical injuries and posttraumatic stress disorder (PTSD). Tracking the correspondence of violence, crime, and incarceration to its impacts on trans populations can be a challenging task, even as some jurisdictions classify gender identity as a protected class when evaluating whether certain acts of violence are to be classified as hate crimes. More data collection efforts related to these topics are beginning to add gender identity designations that help identify the prevalence of these issues among trans populations. These developments can help expand what is known about the role that violence, crime, and incarceration play in shaping trans health.

Trans populations, including trans youth populations, may also be at higher risk for abuse of alcohol, drugs, and tobacco. Such elevated risk has been demonstrated to correspond to psychosocial risk factors related to stigma and victimization faced by trans people, mirroring the higher rates of substance abuse among other communities that experience minority stress and marginalization. Trans women in particular may also face higher risks of HIV and STIs, which can be compounded by obstacles to health care and screening. Owing to these patterns, some substance use, sexual health, and harm reduction programs focus on tailoring outreach to trans populations in particular or through broader LGBTQI community networks. The success of these efforts can be highly context dependent.

Seeking Medical Care While Trans

Health disparities can greatly be affected by the availability and quality of medical care to different populations. Health care providers are often uninformed about how to work with trans patients, both in the care and management of trans health and regarding medical needs ostensibly unrelated to gender identity. Medical records often do not include patients' gender identities and gender pronouns separately from legal sex designations and names that may no longer be used by patients. These standardized practices, which are often difficult to change institutionally, may lead to experiences of misgendering, deadnaming, and other microaggressions that discourage trans people from seeking health care in medical settings. Among trans elders, aging-related health needs can also be subject to marginalization and stigma, or the perception that most trans people are young and not in need of aging-related health services.

Reproductive health among trans people is also a relatively understudied topic. People who transition may seek fertility preservation and ongoing fertility treatment, experience unplanned pregnancies, and face obstacles to contraceptives and abortion. Reproductive health can still be very heavily gendered in clinical settings, and trans patients may face obstacles in having their needs met due to health care providers' gendered assumptions about childbearing, fertility, and reproduction.

Transition-Related Health Care

In addition to the many other health considerations that the general population faces, trans people's health may be influenced by the availability and ease of access to transition-related health care. Trans individuals may pursue a wide variety of transition-related medical treatments and procedures, and scholars are only now beginning to understand the long-term impacts of treatment patterns on health and overall well-being. Transition-related health care can take many forms, including but not limited to hormone replacement therapy, gender-related mental health care, reproductive health, surgical procedures, and voice therapy.

Different forms of transition-related medical treatment can have different impacts on the health of trans people. Trans people who were assigned male at birth are estimated to pursue hormone replacement therapy at higher rates than trans people who were assigned female at birth. However, different hormonal replacement therapy regimens are pursued depending on the desired outcomes. At this point, hormone replacement therapy is thought to be more successful in producing masculinizing results than feminizing results, but the level of satisfaction with the outcome of any transition-related medical treatment can be highly subjective.

It is important to recognize that many trans people do not seek any form of transition-related medical care, for a variety of reasons. Some trans people do not feel the need to undergo any physical changes through hormone replacement therapy or surgery. Some trans people are unable to obtain

transition-related treatment due to financial, legal, and social barriers. For trans minors, decisions surrounding transition-related health care are often dependent on the permission of parents and other legal authorities. Overall, the availability of transition-related health care can influence the quality of life and overall well-being of trans people, but the role of timing and age-related considerations in the health and satisfaction of trans people remains an understudied topic.

Some trans individuals, especially those from marginalized socioeconomic backgrounds, may pursue forms of treatment that are not supervised by health care professionals. Some of these treatments may pose risks associated with pursuing medical treatment outside of traditional medical settings and supervision. Expanding the availability of gender-affirming health care and conducting outreach to affected populations may reduce the risks associated with nonsupervised transition-related health care.

Policies Surrounding Transition-Related Health Care and Their Impacts

In some countries, psychological evaluations or other medical procedures are required in order to change vital legal documents. Individuals seeking transition-related health care or even legal recognition must often meet certain gender-related benchmarks as certified by trained therapists in order to be approved. This can pose challenges for people who do not meet the standards set by legal jurisdictions, practitioners, and institutions. Until very recently, many countries required transgender people to undergo sterilization in order to change their legal gender. In 2017, the European Court of Human Rights ruled that these requirements are violations of human rights, causing many European countries to abandon this requirement. However, many other countries outside of the European Union still have these policies in place.

Depending on legal, political, and economic circumstances, some transition-related health care is covered by national health care systems or insurers, while it can be illegal or prohibitively expensive for some trans people to receive transition-related health care. Certain countries, such as the United Kingdom, cover some transition-related health care as part of their broader national health systems, but many countries do not provide any assistance or place significant barriers to transition-related health.

International organizations, such as the World Professional Association for Transgender Health (WPATH), establish and distribute recommendations for standards of care to health professionals. These recommendations and protocols change over time in accordance with developments in trans patients' experiences, recommendations from community organizations, and developments in medical research. However, these protocols are not uniformly adopted, and implementation can vary widely by provider and local context.

Health Differences Corresponding to Specific Gender Identities

Health in trans populations may also be influenced by the specific contours of particular gender identities within the broad umbrella of trans identity. While some studies find that trans men's and trans women's overall health does not differ from that of the general population, nonbinary and other gender-nonconforming people appear to face a distinct health disadvantage. Nonbinary and gender-nonconforming people face more discrimination, have additional barriers in seeking medical care, and may engage in more health-harming behaviors due to the possibility of compounded minority stress and a lack of understanding of nonbinary gender identities by health care providers.

Even among trans people who are not gender nonconforming or nonbinary, differences in gender presentation and how others perceive and interpret one's gender presentation may present further health disadvantages that are separate from the implications of identifying as trans or with a particular trans gender identity. Certain factors, such as race and ethnicity, can influence how these different aspects of gender factor into different forms of inequality and discrimination. This suggests that it is important to look at trans health from multiple angles, including personal identity, institutional classifications, physical embodied characteristics, and social interactions.

Furthermore, many countries have a history of gender-nonconforming or broadly defined

trans populations that have a specific cultural context that can shape the health of particular subpopulations. *Hijra* populations in countries like India, Pakistan, and Bangladesh; *kathoey* populations in Thailand; and *travesti* populations in Latin America are some of the many distinct gender minority populations around the world with their own specific health contexts that should be evaluated in both a local and a broader global health context.

Health-Promoting Factors

A variety of health-promoting factors may combat the health impacts of stigma and other structural barriers faced by trans populations. Peer and community-based support can help mitigate the impact of minority stress. Peer-based support can be particularly important to trans elders, who often experience high levels of social isolation in addition to other experiences of marginalization. Providing gender-affirming physical health, mental health, and social services in both transition and nontransition care can also help bolster the overall well-being of the trans population.

Reducing levels of trans homelessness and violent victimization can also contribute to reducing the health burdens that these experiences place on trans individuals. Just as with other marginalized groups, economic and class conditions can exacerbate the impact that identity-based marginalization has on the well-being of individuals and re-create inequalities within gender minority groups. Improving life factors that intersect with trans marginalization may be a major step toward promoting the overall health and well-being of trans populations.

Furthermore, it is important for medical practitioners and researchers to include and consider trans populations in every aspect of their work. There are still many gaps in health knowledge that can lead to systematic neglect of this marginalized population, including the need to distinguish between the biological factors associated with sex and the social and psychological components of gender identity when looking at the gendered dimensions of health. Greater inclusion of trans populations and trans-related considerations in medical practice and public health research can itself promote the health of trans populations by informing adjustments to existing medical practices and public health interventions.

Health in Non-Western Contexts

Worldwide, there are an estimated 25 million trans people—that is, persons identifying in a gender other than that matching their birth-assigned sex. "The West" (often called the global North and broadly comprising the United States and Canada, most of Europe, and a scattering of high-income countries across Asia and Australasia) comprises around a quarter of the global population. It is likely home

to a similar proportion of trans people, with the remainder living in low- and middle-income countries of Latin America and the Caribbean, Africa, and much of Asia and Oceania (the global South). Historically, the global North has accounted for most of the scholarly literature on trans people, their health and health care. Notwithstanding, nearly half of the top 30 countries linked to trans health research since 1990 are from the global South. This entry examines trans people, as well as their health and health care, in these regions.

Trans People in the Global South

Trans people form large communities across much of the global South, for example, across Latin America, South and Southeast Asia, and the Pacific. Their social visibility in some cases is associated with, and may stem from, indigenous "gender pluralist" cultures in which those who nowadays would be called trans enjoyed acceptance and inclusion, as well as performed important and valued roles as teachers, mediums, healers, or performers. Westerners were sometimes shocked by, and attempted to suppress, the gender diversity they encountered on first contact with such cultures. Colonization and Christianization, as well as modernization, involving industrialization and Westernization (in more recent years framed as a process of globalization) have all taken their toll on gender pluralism. Old ideas on health and morality have been replaced by newer Western ones. Gender pluralism has declined, along with many of the roles earlier played by gender-diverse people in their traditional societies. Nonetheless, trans communities in the global South survive and are often characterized by a social vibrancy and activism not seen across much of the global North.

Across much of the global South, trans people nowadays experience stigma. They are viewed by others as contradicting nature, contravening divine law, and being sexually perverse, deceptive, and/or mentally sick. These stigmatizing beliefs affect trans people's lives in numerous ways. Trans people commonly face prejudice and discrimination (both interpersonal and institutional) across multiple aspects of their lives, including in their home, school, workplace, accommodation, social services, and health care. Many experience harassment and abuse and often encounter violence, including sexual violence. Youth are often rejected by their families, are unable to live at home, and drop out of education early. Trans people find themselves marginalized, barred from social and economic opportunities, deprived of legal rights, and living in comparative poverty. Across much of the world, trans people face challenges in gaining employment. When they can find work, it is often in the beauty industry or as performers, sex workers, or (in much of South Asia) in ritual and alms collection. Many difficulties faced by trans people are compounded by absence of legal protections against discrimination or poor enforcement of existing laws.

Across much of the global South, additional challenges arise from the failure of governments to allow for easy access to legal gender recognition. Large numbers of trans people are unable to change their identity documents, either because it is prohibited, because there are no laws or regulations that allow it, or because laws allowing it impose stringent medical and other conditions that act as barriers. Trans people lacking gender-affirming documentation are at heightened risk of discrimination in their daily lives.

Excluded from mainstream society, trans people commonly experience relative isolation and poor mental and physical health and well-being, and they often become involved in life situations and behavior patterns that put them in harm's way. In particular, many trans women become involved in sex work, often as a means to survive and under conditions that leave them vulnerable to sexually transmitted infections, as well as violence, harassment, and extortion (often from law enforcement). Minority ethnicity, poverty, involvement in sex work, and HIV infection (or perceptions thereof) add additional layers of stigma. Poor health services, which are especially ill-matched to the needs of trans people, exacerbate the health challenges that trans people face.

Trans Health in the Global South

Much of the trans health research in the global South originates in South, Southeast, and East Asia and Latin America. Comparatively fewer studies (in English at least) are from Africa, the Middle East, the ex-Soviet bloc, or the Pacific and Caribbean small island nations. The available

literature reveals numerous health challenges for trans people. In common with their counterparts elsewhere, trans people in the global South commonly experience poor mental health. They experience high levels of depression, stress and anxiety, suicidal ideation, and self-harm. These difficulties appear to stem from daily stigma-related experiences, rather than from gender issues per se. Trans people in the global South also have high levels of alcohol and drug abuse, and they may engage in higher levels of health risk behaviors (e.g., because of low self-esteem or poor mental health). Unregulated health care and self-medication are common across much of the global South, putting many trans people at risk of poor physical health. Health care service avoidance may further exacerbate health risks.

Numerous studies reveal high prevalence rates for sexually transmitted infections, particularly for trans women and those trans people engaged in sex work. Rates of HIV infection among trans women may average as high as 18% across much of low- and middle-income Latin America and Asia, around 50 times higher than the corresponding rate for adults of reproductive age in the general population. Some individual studies in Asia and Latin America show much higher prevalence rates.

Violence against trans people (verbal, sexual, and physical) is a problem across much of the global South. Between 2008 and 2019, more than 2,900 murders of trans people were documented in the global South (out of over 3,300 worldwide). Of these, Latin America and Caribbean accounted for the vast majority (around 2,600), with over 1,200 from Brazil. Community groups play an important role in collecting these statistics. Practical difficulties in data collection, particularly in conflict zones and in countries in which civil society is under stress, mean that these figures likely represent an undercount of actual killings. In any case, these figures do not reflect nonlethal violence, in itself a common source of trauma for trans people.

Health Care for Trans People in the Global South

Countries across the global South are generally low and middle income. Health care systems are often comparatively poorly developed and resourced, and so most people (cisgender as well as transgender) encounter difficulties accessing a range of services. Publicly funded "universal" health care is often absent and not free of charge. Specialized and ongoing health care, or the health care insurance that can enable access to it, is beyond the reach of many individuals.

However, trans people often encounter additional difficulties not experienced by their cis counterparts. First, health care workers often lack cultural competence and are insensitive, unsupportive, or hostile toward trans people and their needs. At worst, there are reports of trans people being denied health care. Second, many health care providers are untrained in trans health care and so lack the clinical competencies that would enable them (a) to assess patients' needs and provide gender-affirming health care, (b) to address issues that might arise in relation to that care (e.g., managing cardiovascular conditions or "legacy" conditions such as prostate issues in trans women), (c) to manage sexual health care needs (e.g., regarding anal or neovaginal intercourse), and (d) to offer counseling and therapy related to their patients' stigma-related experiences. Third, specialists (e.g., mental health professionals, endocrinologists, and surgeons) competent in trans health care may be especially scarce or not available at all.

For all these reasons, trans people commonly report avoiding health care services. Where they do access services of any kind, they tend to use private health care rather than government clinics. Many turn to parallel health care arrangements. They access hormones that have been recommended (and sometimes provided) by other trans community members and take them without medical monitoring. In some places, particularly in Latin America and some parts of Southeast Asia, some trans women employ injected silicone to alter their body, with the procedure often performed by another member of the community. Nonmedical silicone or nonsilicone substances are sometimes used. Some South Asian *hijra* engage in ritual removal of the penis and testicles. All these practices present health risks to those involved.

The World Professional Association for Transgender Health (WPATH) Standards of Care (SOC), intended to guide the delivery of trans health care worldwide, has been criticized for a global North focus that assumes well-resourced

health care systems of the sort not common in low- and middle-income countries. Since 2010, various health care resources aimed at global South audiences have been published, most notably for the English-speaking Caribbean (under the sponsorship of the Pan American Health Organization, PAHO) and Asia and the Pacific (under the sponsorship of the Asia-Pacific Transgender Network [APTN]). These resources focus more heavily on health care in low-resource settings, as well as on the impact of stigma-related experiences on trans people's health.

WPATH's eighth SOC revision (published in 2021) attempts greater relevance for trans people in the global South, as well as for their health care providers. Developed with the participation of trans health leaders worldwide, the SOC list a number of principles to be followed wherever trans health care services are provided and regardless of the level of resourcing available. They include that health care providers (a) appreciate the impact of attitudes, laws, economic circumstances, and health care provision on the experiences of trans people, as well as their willingness to access services; (b) work to lessen stigma and enable access to health care; (c) respect diversity and avoid pathologizing the trans experience; (d) respect basic rights to patient autonomy, self-determination, freedom from discrimination, and the highest attainable level of health; (e) involve trans people in the development of services; (f) provide health care that is gender affirmative, rejecting reparative approaches; (g) become knowledgeable about trans people and their health needs; (h) match health care to the individual needs of clients; (i) promote overall health and well-being, beyond reduction of gender dysphoria; (j) adopt harm reduction approaches where needed; (k) engage clients fully in decisions about their own health and well-being; (l) improve clients' experiences of all aspects of the health service, including administrative staff; (m) put clients in touch with communities and other sources of support; and (n) act as advocates for clients where appropriate.

Heteronormativity

Heteronormativity is a system and set of beliefs that uphold heterosexuality and the sex and gender binaries as the norm and default, thereby affecting societal views on and attitudes toward sex, gender, sexual orientation, and family dynamics. The *gender binary* asserts that only two genders exist, men and women, which are based upon the corollary sex binary. *Cisgender* (cis) refers to people with a gender identity that is aligned with their sex assigned at birth (e.g., an individual assigned female at birth who identifies as a girl/woman), while *transgender* (trans) refers to people with a gender identity that is not aligned with their sex assigned at birth (e.g., an individual assigned male at birth who identifies as a girl/woman). Heteronormativity is based on heterosexuality as the norm to which the majority of people in society subscribe, whether voluntarily or forcibly, to a binary gender system wherein the only natural options are to identify as a cis man or cis woman. Sexual orientation, gender identity, and gender expression are distinct from, yet related to, one another. Sexual orientation is an individual's identity in relation to the gender or genders they are attracted to emotionally and/or sexually (e.g., gay, lesbian, bisexual). *Gender identity* encompasses an individual's internal sense of identifying as man, woman, nonbinary, and any other gender. *Gender expression* refers to how a person outwardly displays their gender through mannerisms, behaviors, interests, and their appearance. An individual's gender identity may or may be not be aligned with their gender expression (e.g., identifying as women but presenting androgynously), and sexual orientation is often assumed based on a combination of how they appear and behave (i.e., their gender expression). Terms that describe nonconformity to heteronormative expectations may be associated with queer, trans, or nonbinary embodied identity. This entry discusses the origins of heteronormativity, societal systems that heteronormativity permeates, and activism that can be used to push against and reform heteronormative systems.

Heteronormativity and Heterosexism

Scholars sometimes use *heteronormativity* and *heterosexism* interchangeably because the two terms share a great deal of overlap. The slight distinction between the two concepts is nonetheless an important one. Heteronormativity is a system of cultural biases that favor heterosexual relationships and behaviors, a system that permeates theory, practice, worldviews, and societal systems (e.g., work, education, family). In a heteronormative system, heterosexuality or sexual attraction to, or sexual practices with, a person of the opposite binary sex (e.g., a male attracted to a female) is considered the default, "normal" sexual orientation. By contrast, heterosexism is the systematic assumption that heterosexual identity and people are superior to LGBQA+ people, which enforces heterosexuality and maintains heterosexual dominance at all levels of social interaction. In essence, heteronormativity asserts the normality of heterosexuality, and heterosexism asserts the superiority of heterosexuality, creating the societal view that LGBQA+ people are both abnormal and inferior.

Heteronormativity, Colonization, and Whiteness

Heteronormativity, as a system, has its roots in colonization. Colonization is a process of taking control of an already populated geographic region and subjugating existing populations to the belief systems of the colonizing group. Western societies (e.g., the United States) that participated in colonization promoted white supremacy, the belief system that white people are superior to people of color and that they should therefore be the dominant group in society, in most facets of society: religious, scientific, legal, cultural, and linguistic, for example. In this way, heteronormative binary sex and gender systems, which are entangled in beliefs about sexuality, reproduction, family, and even marriage, are also rooted in notions of whiteness. Heteronormativity affects perceptions of attractiveness and shapes desire—perceptions and desires that extend beyond cis and heterosexual identities and bodies. Because white racial identity is more privileged and valued than any other racial identity in most societies, including in the United States, whiteness is often perceived to be more attractive and desirable compared with any other racial identity. The desire for whiteness is

therefore often entangled with heteronormative expectations and desires of heterosexuality and cis identity, and racism becomes intertwined with heteronormativity, sexism, and heterosexism.

Societal views that uphold whiteness as being the most attractive and desirable has contributed to devaluing and stereotyping people of color. This history spans from colonial subjugation of people of color via the slave trade to present-day influences witnessed in media representation and norms for dating and romantic relationships. Women of color, compared to white women, are hypersexualized. For example, Black women still face historical tropes of the Jezebel, Mammy, and Sapphire in which Black women's sexuality is labeled as ravenous and never-ending. Additionally, and again compared to white women, Asian women are often seen as submissive and faced with the tropes of the China Doll or Mail-Order Bride. Prejudicial views based on stereotypes relating to attractiveness, sexuality, and exoticism that negatively affect people of color can influence harmful behaviors in the context of queer and heterosexual relationships. Such can be exemplified by phrases on dating apps such as "No Rice" or "No Chocolate" to denote that individuals would not date members of certain racial groups.

Heteronormativity, Family, and Reproduction

The family unit is a prime example of a societal institution wherein heteronormative expectations are encouraged, enforced, and internalized. Notions of traditional, nuclear family units are idealized as heteronormative based on assumptions that all members of the family are cis, heterosexual, and gender conforming. Because the traditional, nuclear family is also a monogamous one, nonmonogamous (e.g., polyamorous) relationships go against expectations regarding heteronormative family structures. The traditional nuclear family trope reinforces patriarchal norms, whereby men are granted power, dominance, and privilege simply because they are men; men are most valued above all other gender identities; masculine behaviors are valued over femininity and any other gender expressions; and conformity to sex assigned at birth is valued over gender nonconformity.

LGBTQIA+ people experience discrimination, rejection, internalized homophobia, and/or internalized transphobia in families that perpetuate heteronormative beliefs. *Internalized transphobia* refers to the way a trans person may absorb and hold negative beliefs about their own identity and/or the identities of other trans people. In order to push back against or to account for nuclear family norms, LGBTQIA+ individuals may form alternative family units (e.g., chosen families, polyamorous relationships, and other nontraditional family structures). Alternative family units are not regarded as legitimate under heteronormative standards because they do not meet the requirement of *reproductive futurism*. In capitalist societies such as the United States, reproductive futurism is the idea that the successful future of capitalism is inherently linked to producing children to sustain the labor force. Heterosexual relationships are associated with reproduction, and queerness is associated with an inability to reproduce. Under the logic of reproductive futurism, relationships that do not produce children threaten continued and future economic success of a given country.

Within the context of heteronormative expectations regarding family and reproduction, it is important to discuss intersex people also. Intersex people may have reproductive, sexual, or genetic anatomy or sex markers that are perceived not to align with male or female sex designations. Without a clear sex assignment, an intersex person often does not fit neatly into the heteronormative sex and gender binaries. Families and doctors may worry that an intersex child will not be able to live a "normal" life, specifically regarding romantic and sexual relationships, if they do not intervene. As infants, many intersex people have often been subject to nonconsensual sex reassignment surgeries in order to "create" a sex assignment that conforms to the sex binary. The sex reassignment is often arbitrarily determined (e.g., male sex reassignment may be conducted if a phallus is more prominent), and the reassignment may end up not aligning with the gender identity that later develops for an intersex person. Intersex surgeries have come under increased scrutiny in recent years because they serve only to force people to conform to a heteronormative system rather than serving any medically necessary purpose.

Heteronormativity and Education

Like family systems, school systems often directly, even if inadvertently, reinforce heteronormative ideals. For example, teachers may maintain gendered divisions within the classroom (e.g., asking the girls to sit on one side and the boys to sit on the other side of the room). School gyms, bathrooms, field trips, and other events also enforce sex-based ways of assigning resources, facilities, and materials. In physical education, heteronormative ideas about bodies determine standards for exercise and health, and students are commonly segregated into gendered locker rooms. Additionally, classrooms are often absent of openly LGBTQIA+ teachers and school curricula that include LGBTQIA+ issues and authors, thus silencing LGBTQIA+ stories, issues, and representation within classroom contexts. With strict sex and gender segregation and lack of LGBTQIA+ representation within many educational systems, LGBTQIA+ students, especially nonbinary students, can feel alienated and be subjected to discrimination for failing to meet heteronormative expectations. One way that LGBTQIA+ students have found support in school systems is through the creation of student-run confidential support groups (e.g., Gender and Sexuality Alliances).

Heteronormativity and Compulsory Heterosexuality

Compulsory heterosexuality refers to the idea that heterosexual identity and behaviors are required in a heteronormative system that expects everyone to conform to heterosexual behaviors and the gender binary. The term *compulsory* points to expectations of conformity to heterosexual norms that are embedded in many institutions (e.g., the family unit, schools, workplaces). Individuals who do not fit compulsory heteronormative gender and sexuality expectations in identities, behaviors, and/or appearances (e.g., people who are queer, trans, nonbinary, gender nonconforming) will likely encounter barriers or outright discrimination in many contexts (e.g., housing, workplace, school systems, public facilities, places of public accommodation). The threat of punishment for deviating from expectations can compel people to conform to heteronormativity. Even individuals who are able to easily conform to heteronormative expectations (e.g., those who conform to binary gender expressions and outwardly identify as, or appear to be, heterosexual and cisgender) may still feel restricted in that they may not feel comfortable or safe fully expressing their gender or sexuality depending on the situation.

Heteronormativity, Privilege, and Oppression

Heteronormativity confers power, privilege, and preferential treatment upon heterosexual cis individuals. Such treatment often comes at the expense of positive or inclusive treatment for LGBTQIA+ people. Treating cis heterosexuality as the norm or the most natural sexuality places other sexual orientations (e.g., lesbian, gay, bisexual, pansexual, queer) in opposition to heterosexuality and therefore labels them as unnatural or abnormal. Believing that heterosexuality, the gender binary, and monogamy are all normal can prompt people to act in discriminatory or unjust ways against people who do not subscribe to one or more of these heteronormative expectations (e.g., that all women should bear children). Actions that enact heteronormativity are heterosexist because they unfairly privilege heterosexual, cis, monogamous people and unjustly disadvantage people who identify as trans, nonbinary, queer, and/or polyamorous. Refusing to promote a woman to a position of leadership and rating a male student as more capable than a female student simply because of his sex are considered heterosexist acts. Heterosexual and cis identities are not inherently damaging, but imposing heteronormative ideas, beliefs, and expectations can be damaging to all people, especially for those who do not fit within or subscribe to these identities.

Advocacy

Heteronormativity permeates and influences many spheres of society, from the family unit up to and including the federal government, and the perceived unnatural status of LGBTQIA+ identities is used to justify anti-LGBTQIA+ policies in a variety of social contexts (e.g., school systems, workplaces, public facilities, family planning services). As discussed earlier, heteronormativity and societal preference of heterosexuality extend to enforcement of

the gender binary, reproductive expectations, and the traditional nuclear family unit. Because of this, it is important to remember that heteronormativity is damaging to all people, especially LGBTQIA+ people. An important part of combating heteronormativity is first identifying how pervasive it is within our lives and the systems in which we exist and interact. It is important for people to identify the ways in which they enact heteronormative beliefs and how that negatively affects them and those around them by placing restrictions upon what is acceptable or unacceptable regarding gender identity, gender expression, sexual orientation, and family structure. Understanding the implications of retaining systems that place a dichotomy of normal versus abnormal on gender, sex, and sexuality is the first step to initiating change to deconstruct the heteronormative systems that are damaging to so many people.

Heterosexism

Heterosexism is a complex, binary network of assumptions that permeate administrative, institutional (e.g., law, familial, economic, educational), and cultural systems and that shape behaviors, practices, beliefs, and identities. The binary biological determinism that underlies heterosexism dictates that a person with a penis must be a man, a person with a vagina must be a woman, and a person with ambiguous genitalia must be assigned one or the other. Forced sex assignment limits who people are allowed to be and also erases the experiences and identities of people with physical characteristics that fall outside of their identity (e.g., nonbinary people, intersex people, women who have had mastectomies). The broad range of gender identities complicates heterosexist norms because heterosexism is reliant on static, assigned, binary sex categories (e.g., male and female). The binary understanding of sex, gender, and sexuality imposed by heterosexism underlies the marginalization of individuals with nonnormative sexual and gender identities (i.e., LGBTQIA+ people) in all domains of society (e.g., school, work, media, sport). In the sections that follow, this entry discusses the origins of, relational implications of, and the movement to resist heterosexism.

Colonialism

Colonialism, the process of gaining control over and exploiting other cultures and geographic spaces, requires discrete boundaries, categories, and labels. Much like planting a flag in the ground and claiming ownership over a territory, names define conceptual spaces and assert expectations on bodies, peoples, and behaviors. In predominantly white, Western cultures, the word *heterosexual* signifies monogamous sexual relationships between one cisgender (cis) man and one cisgender (cis) woman. In a heterosexist paradigm, homosexual relationships are considered to be the polar opposite of heterosexual relationships, and bisexual individuals rest somewhere in the middle of the resulting continuum. *Homosexual* is a term with an oppressive clinical and religious history born out of colonialism and the imposition of white, Western belief systems that privilege reproduction,

marriage, and nuclear family systems. The term *homosexual* has been supplanted by terms more aligned with identity such as LGBTQIA+. Sexual minority communities include a broad range of sexual and romantic identities (e.g., pansexual, asexual) that are not heterosexual. An individual exhibits heterosexism when the person's behavior is motivated by a commitment to, or when it reinforces, heterosexual norms.

Consistent with colonial impulses, heterosexist behaviors are motivated by heteronormative beliefs or convictions that heterosexual relationships are morally, socially, and/or intrinsically superior to other types of relationships. Although hetero-*sex*-ism implies that only sexual encounters are constrained to heterosexual relationships, the term places restrictions on nearly all forms of affection that emerge between people in any variety of relationships (e.g., friends, acquaintances). Under heterosexist norms, affection and sexual connections are to be maintained within monogamous relationships between one cis man and one cis woman. Cultures, systems, behaviors, and interactions are considered heterosexist when they are based on the assumption that people strive toward and/or behave as stereotypical heterosexual individuals.

Cross-Cultural Implications

Heterosexism carries a broad range of meanings for different groups. For example, on the basis of heterosexist ideals, a married woman is expected to give birth to children, and a cis lesbian woman is considered less valuable to society for her assumed inability to do so. Unique experiences of heterosexist norms extend to trans people in distinctive and complex ways. For example, some communities and cultures promote manliness/machismo or a dedication to white, sexist, hegemonic masculinity. *Hegemonic masculinity* incorporates notions of race, class, sexuality, ability, and so on that maintain contemporary, idealized white, cisgender, masculine men as the status quo in society. Trans people, gay men, women, bisexual people, and any other sexual or gender minority individuals are devalued under current hegemonic masculine social systems in which cis heterosexual men are most privileged.

The pressure to conform with masculine, heterosexist ideals gives rise to laws and customs across a wide range of communities, cultures, and countries (e.g., anti-sodomy laws, debates over the appropriateness of same-sex marriage). Heterosexist constraints interact with other forms and sources of oppression (e.g., racism, immigrant status, [dis]ability, and poverty).

Related Binary Terms

Heterosexism is different from, yet related to, sexism. Whereas heterosexism describes behaviors that privilege a normative (hetero) sexual orientation over minority sexual orientations, sexism describes behaviors that privilege men over women and prescribes a false binary of male and female as the only sexes. In a sexist system, masculinity is also privileged and favored over femininity. For example, gay men are considered more feminine than heterosexual men, and lesbian women are sexualized and objectified by individuals who ascribe to sexist ideals. Gay men are often perceived to be more feminine, and therefore devalued, in comparison to heterosexual men. Lesbian women who are feminine are often viewed as alluring and exotic because of their same-sex sexual attractions and behaviors.

Heterosexism is further related to cissexism, or the idea that cis individuals are preferable to transgender people. Like sexism and cissexism, heterosexism is used to organize social systems, make decisions, design spaces, and determine resource distribution. Heterosexism is also the basis for violence, discrimination, and experiences of minority stress.

Gender Identity

Although heterosexism does not address gender identity directly, heterosexist expectations assume a gender binary and require conformity to the sex that a person was assigned at birth. Trans people break heterosexist expectations when they claim a gender identity that does not correspond with their sex assigned at birth. Nonbinary people further complicate heterosexist expectations when they identify with multiple gender categories, as being between gender identities, and/or may not identify with any gender. Through the lens of heterosexism, trans people may be viewed as homosexual, mentally ill, and/or confused.

As is the case with any other population, trans people identify with a wide range of sexual orientations (e.g., heterosexual, lesbian, gay, bisexual), and experiences of heterosexism among trans people vary widely. Heterosexual trans people may fit most heterosexist expectations (e.g., marry a partner of the opposing binary gender and practice monogamy) but may still be affected by claims that their heterosexual relationships are not legitimate because of the sex they were assigned at birth. Trans people who identify as one or more sexual minorities may be subjected to authenticity claims and the additional discriminatory attitudes held against sexual minority people.

Nonbinary people may fall outside of heterosexist expectations, given that nonbinary people may not identify with a gender at all. Nonbinary people in relationships will not fit into established heterosexual categories that require cross-binary gender relationships. Because nonbinary people do not fit heterosexist norms, they may be further subjected to discrimination and violence. Oppression of nonbinary people is based on biological determinism or the idea that an individual's biology is innately tied to their being and personhood. Heterosexist cultures require individuals to identify their gender in relationships, and people with nonbinary identities confound such societal demands.

Identity and Privilege

The amount of power, prestige, or social desirability that a person possesses is granted to them, in part, based on their conformity to heteronormative ideals. This means that individuals may experience differing levels of heterosexism based on the identities they possess. Mounting evidence indicates, for example, that bisexual people experience elevated rates of depression and other distress relative to lesbian and gay people because they are considered neither acceptably heterosexual nor acceptably homosexual.

Although the term *intersectionality* was not initially intended to refer to compound stressors that result from possessing multiple minority identities, psychologists and other scholars sometimes use intersectionality theory as a frame to discuss how identities influence experiences of both privilege and oppression in different contexts. For example, using an intersectional frame, scholars note that people possess a variety of identities (e.g., sexual orientation, gender identity, race, ability status) that are the catalyst for experiences of both privilege and oppression in context-specific (e.g., in groups that are majority white, in religious and cultural settings, at work) social arenas. It is important to consider intersectionality when discussing heterosexism because heterosexism may manifest in different minority communities in different ways.

Interpersonal Impact

Inability or refusal to conform to heterosexist expectations can result in violence and other destructive forms of discrimination. LGBTQIA+ people face a wide range of discrimination that produces both direct (e.g., physical damage, death) and indirect (e.g., mental health concerns, limits to resources) effects. Aside from their potential lethality, heterosexist pressures are one of the many sources of anxiety, depression, and other types of distress reported by LGBTQIA+ people.

LGBTQIA+ people who are perceived to be transgender and/or nonbinary (e.g., a man carrying a purse, a woman wearing a flannel shirt) as result of their appearance or behaviors are subjected to a variety of minority stressors. Some minority stressors include rejection by others, nonaffirmation of gender identity (e.g., others using the incorrect pronouns or name), being denied access to resources or services on the basis of gender identity, or experiencing violence at the hands of people who hold hostile beliefs toward LGBTQIA+ people. In particular, there is a growing crisis in which transgender women of color, especially Black transgender women, have been murdered at the hands of cis men because of these hostile beliefs. Even trans people who are able to pass, or be perceived, as cis experience proximal minority stressors, including fear of being outed as transgender or nonbinary by others or internalizing negative beliefs about one's own trans identity, known as *internalized transphobia*.

Internalized Impact

As LGBTQIA+ people live in a heterosexist world, they may internalize the discriminatory behaviors

and heterosexist messages to which they are exposed on a daily basis in the news, popular media, and their everyday lives. Even when individuals try to resist mirroring or mimicking heterosexist expectations, they may show up in LGBTQIA+ communities. For example, some LGB people discriminate against and/or exclude trans people in social and communal spaces. Likewise, some binary transgender people discriminate against and exclude nonbinary transgender people. Moreover, LGBTQIA+ individuals sometimes discriminate against fellow LGBTQIA+ individuals when they do not conform to heterosexist expectations. An example of this is slut-shaming those who are in polyamorous relationships, because they do not conform to the heterosexist expectation of monogamy. Furthermore, trans individuals can discriminate against fellow trans individuals by making fun of those who do not pass, or who get read, as cis.

Resistance

There is a great deal of resilience in LGBTQIA+ communities. Current heterosexist cultural structures create toxic environments for LGBTQIA+ people, but these individuals have developed a variety of skills to overcome heterosexist discrimination. For example, increased levels of pride and identification with LGBTQIA+ communities operate as a buffer against oppression. For trans people in particular, events such as Transgender Day of Remembrance, International Transgender Day of Visibility, and International Pronouns Day are collective efforts by trans communities to show that their identities will not be erased. Researchers have generally focused on the negative aspects of LGBTQIA+ experiences (e.g., depression, anxiety, minority stress), but recent scholarship has included calls for a more resilience-focused approach to LGBTQIA+ research. As research on LGBTQIA+ resilience continues to expand, more insight will be provided into the unique ways that LGBTQIA+ people maintain resistance to heterosexism and other toxic cultural dynamics.

Advocacy

Heterosexist behaviors are perpetuated when individuals fail to resist, alter, and provide education to counter prejudiced, sexist beliefs. Scholars are increasingly calling for researchers, practitioners, and allies to focus on ways to reduce the impact of heterosexism and other forms of oppression that affect LGBTQIA+ people. In particular, organizations have been created to support trans individuals who are among the most at risk for discrimination and violence. Providing a complete list of advocacy organizations is beyond the scope of this entry, but some groups include the National Center for Transgender Equality, Trans Women of Color Collective, Sylvia Rivera Law Project, Trans Lifeline, Coalición Trans Latin@ (Trans Latin@ Coalition), and Transgender Law Center. Activists and advocates suggest that an important part of learning about heterosexism is learning to push back against the damage that is done when heterosexist actions go unchecked.

High School Sports

The ability of trans high school athletes in the United States to compete according to how they identify their gender began to emerge as a highly contentious issue in the 2010s, as out trans students started to participate in organized sports and, in some instances, bested their cis counterparts. The debate has largely involved trans women athletes on the basis of the unproven assertion that they have an unfair competitive advantage over cis women because of having been assigned male at birth. Policies for trans participation in sport vary by state and school district, as well as by presidential administration, and seemingly the issue will ultimately be resolved by the U.S. Supreme Court. Public opinion is also likely to play a role in the outcome, and the growing visibility of trans high school athletes is helping to humanize them in the public eye and address the stereotypes held by many cis district officials, school administrators, parents, and students.

Federal Law

Ironically, both supporters and opponents of trans athletic participation often cite the same law in their defense, namely, Title IX of the Education Amendments of 1972, which banned sex discrimination in educational programs and activities receiving federal funding. Trans people and allies argue that sex discrimination under the law includes discrimination on the basis of gender identity, as trans athletes face being mistreated because of the sex they were assigned at birth. Opponents maintain that Congress did not intend to include trans people when they passed the law; instead, it was designed to address the discrimination that girls and women encountered in educational institutions, including unequal opportunities to participate in sports. They believe that cis girls and women are discriminated against because of the supposed competitive advantage of trans female athletes.

Beginning in the 2000s, the executive and judicial branches of the U.S. government started to side with trans people. In 2016, the Departments of Education and Justice under the Obama administration issued a "Dear Colleague" letter to educational institutions stating that the government interpreted Title IX as covering a student's gender identity, and thus schools could not discriminate against trans students. In terms of sports, this meant that they needed to base the participation of trans students upon competitive skill, rather than stereotypes about the differences between trans and cis people or others' discomfort with trans people. In 2017, soon after Donald Trump took office as president, his administration withdrew the "Dear Colleague" letter and stopped investigating alleged cases of discrimination against trans students.

Federal courts, however, have continued to interpret gender identity discrimination as sex discrimination, particularly in the area of employment law, as Title VII of the Civil Rights Act of 1964 prohibits employers from discriminating on the basis of sex, as well as because of race, color, national origin, and religion. By 2020, 5 of the 12 federal courts of appeals that had considered the issue had ruled that trans people were protected from job discrimination under Title VII, a position that the U.S. Supreme Court affirmed in a 2020 ruling. While not directly affecting Title IX, the Supreme Court's decision will presumably make it much harder for the government to argue that trans students, including trans high school athletes, are not protected from sex discrimination under federal law.

State Policies

U.S. states vary widely in their policies on the participation of trans high school athletes. As of 2020, about a third of states enable students to participate in keeping with their gender identity without needing to medically transition first. Another third require hormone therapy, 6 have no policy, and 10 require gender-affirming surgery and a changed birth certificate, which, given that such surgeries are rarely performed on minors in the United States, essentially bans trans students from being able to compete. The effects of these different policies will be explored by examining the experiences of trans athletes in states with polar-opposite guidelines: Texas and Connecticut.

Texas

In Texas, a student's birth certificate determines their gender for participation in sports, which led to the surreal situation of Mack Beggs, a visibly trans male wrestler, competing against women. As a high school freshman in Euless, Texas, Beggs came out to his family and began social transitioning to live authentically as the man he knew himself to be. This followed a period of internalized transphobia in the seventh grade, when he considered suicide and was hospitalized for self-harm. Beggs developed an interest in wrestling in his sophomore year, at the time that he began medically transitioning by taking low-dose testosterone injections. Texas school superintendents had voted in 2016 to make a student athlete's birth certificate the determinant of their gender, which meant that Beggs was allowed to wrestle, even though he was on testosterone, but he had to compete as a woman.

Beggs wanted to be seen as male and wrestle other men, but he reluctantly complied with the policy in order to continue wrestling. He won back-to-back state wrestling championships, posting a 92–0 record over his final two seasons. Some of his opponents forfeited rather than wrestle him, and some parents of wrestlers on opposing teams booed him and called him a cheater, even though Beggs was complying with state rules. Some of his opponents, however, did support him, as did his teammates. He later confessed that he sometimes skipped doses of testosterone to show that the hormones were not what propelled him to victory. After graduating in 2018, he joined the men's wrestling team at Life University, and the following year, he had top surgery and was able to change his birth certificate to be legally recognized as male. Beggs, who has been very open about being trans, was one of the individuals profiled in *Changing the Game,* a 2019 documentary about trans high school athletes.

Connecticut

Two other high school athletes profiled in *Changing the Game* were Andraya Yearwood and Terry Miller, trans female track sprinters from Cromwell and Bloomfield, Connecticut, respectively. They were allowed to compete against other women because the Connecticut Interscholastic Athletic Conference (CIAC) had established a policy that enabled trans students to compete as their gender identity without requiring medical intervention, in keeping with a 2011 state law that banned discrimination on the basis of gender identity. Following the Trump administration's revocation of protections for trans students, Connecticut Governor Dannel Malloy issued an executive order to ensure that the state's nondiscrimination law continued to apply to trans students.

Yearwood and Miller, like Beggs, encountered harsh opposition to their sports participation, even though they were complying with state policy. The fact that they were highly successful, which included placing in and winning state championships, only added fuel to the criticism from competitors, their parents, and conservative political organizations and news media outlets because of the belief that the athletes had an unfair physical advantage owing to their male-assigned sex. In 2019, the families of three high school runners submitted a Title IX complaint to the federal government with the support of the Alliance Defending Freedom (ADF), a conservative Christian legal group, and subsequently filed a federal lawsuit to overturn the trans-supportive policy, revoke the previous wins of trans athletes, and ban trans athletes from competing in the future.

The Trump administration supported the complaints of the cis students. In 2020, the Department of Education's Office of Civil Rights (OCR) determined that the CIAC's trans-inclusive policy and the six Connecticut school districts that allowed trans students to compete in compliance with that policy violated the civil rights of cis girls and women as guaranteed under Title IX. The OCR threatened to withhold federal education funding to the state and the six districts unless the policy was changed. A deadline set by the OCR came and went without action, and Connecticut's attorney general promised to fight any effort either to discriminate against trans students or to withhold federal funds. At the same time, the Department of Justice notified the federal court in Connecticut that it was in agreement with ADF's lawsuit. Indicative of its disdain for trans people, the Trump administration's court filing misgendered the trans female athletes by using terms such as "biological males" and "boys."

The fallacy of the argument by the ADF and the OCR that trans female athletes have an

Figure 1 Andraya Yearwood

unfair competitive advantage over their cis counterparts was demonstrated by one of the plaintiffs beating Miller in two state track championship races in the 2 weeks after the lawsuit was filed. Transphobia is clearly behind the legal actions and perhaps also racism. Both Miller and Yearwood are Black, while two of the plaintiffs are white and the third is biracial.

State Laws

In 2020, Idaho became the first state to enact a law banning trans girls and women from participating on female sports teams in its public schools, from the elementary level through college. The law, which is known by the doublespeak title as the Fairness in Women's Sports Act, also includes a controversial provision that requires girls and women whose gender is in question to undergo a sex verification process, which could include a genital exam, as well as genetic and hormonal testing. Citing Title IX, the American Civil Liberties Union immediately filed a lawsuit to block the law, so this case may ultimately decide how "sex discrimination" is defined in federal statutes in terms of the participation of trans students in high school sports.

HIJRAS

Hijras are communities of male-assigned individuals on the Indian subcontinent (including Bangladesh, India, Nepal, and Pakistan) who take on many traditionally feminine attributes. While hijras' origins can be traced to ancient religious texts and practices, in recent decades, they have received notable public and scholarly attention and are arguably the most well-known example of a nonmale/nonfemale gender role in the world today. However, this visibility has not always resulted in greater acceptance and, in some cases, seems to have had the opposite effect. Hijras continue to experience high rates of harassment and violence, even though many of the countries in the region granted them legal recognition and some political rights in the 2010s.

Defining Hijras

Hijras have commonly been misunderstood by researchers, government officials, and the popular media, as reflected in the many inaccurate terms used locally and internationally to label them. Historically, these descriptors have included *eunuchs, hermaphrodites, intersex people, transsexuals,* and *transvestites*. Hijras are most widely referred to today as a "third gender, neither man nor woman," but, as noted by anthropologists Adnan Hossain and Serena Nanda, this description fails to encompass the understanding that hijras have multiple identities, some of which contradict each other. Hijras do not always identify themselves as a third gender and may adopt cultural markers that are considered feminine or that combine traditionally feminine and masculine characteristics. Similarly, contemporary scholars and activists often subsume hijras under a universalizing "transgender" framework, which erases the specificities and inconsistencies of hijras identifying as both women and "not women."

Hijras see themselves as "like women" because they assume many stereotypically feminine characteristics; they wear traditionally women's clothing and accessories, shave their body and facial hair, grow their hair long, use mannerisms that are read as female, and adopt conventionally feminine names, and some undergo feminizing hormonal treatments. Yet, even though hijras typically seek to sit in the women's section on public transportation and may obtain official female identification documents, they do not look to socially "pass" as women and in some contexts deliberately disrupt the idea that they are female. For instance, they engage in behaviors that are not traditionally considered proper for South Asian women, such as using vulgar language and dancing in public, and employ nonverbal gestures, such as the *thikri* (a loud clap), that are associated with hijras. At times, hijras also tend to dress in customarily male ways; in Bangladesh, for example, hijras present as men on some special occasions and when they undertake the Hajj, the Islamic pilgrimage. The most noted way that hijras are "not women" is that they may decide to undergo a penectomy and castration (orchiectomy) but do not seek a vaginoplasty to present physically as more traditionally female.

Although hijras are commonly known for being emasculated (i.e., having their genitals removed), this practice is not universal and not always a requirement to be a hijra. In India, hijras consider having their genitals removed to be a sacrifice to the Hindu goddess Bahuchara Mata, who then grants them the power to confer fertility to others, which is central to the traditional hijra role in India of singing and dancing at marriages and the births of male children for compensation. However, in Bangladesh, hijra status does not derive from being emasculated but from their ability to conduct *hijragiri,* the traditional occupations of hijras, which include conferring blessings on newborns and mastering *ulti,* the secret hijra language. In fact, Bangladeshi people consider hijras who undergo emasculation to be inauthentic or fake, as they define "real" hijras as men born with missing or ambiguous genitals.

In recent decades, hijras in India have seen their status as sacred figures wane and have faced greater difficulties earning money from giving blessings. As a result, hijras have increasingly turned to sex work, where they take the passive role in sex with male clients. This sexual role is central to the identity of many hijras.

Oppression and Legal Recognition

Under British colonial rule, hijras in South Asia were labeled as a deviant, criminal caste and experienced persecution, and this state-sponsored

hostility and mistreatment carried over into the newly independent South Asian countries. For example, the Indian constitution denied hijras the ability to vote, own property, marry, have a passport and driver's license, and other citizenship rights. Hijras also experience high rates of physical and sexual violence and harassment, including from the police; have limited access to appropriate housing and medical care; and are frequently subject to economic discrimination, theft, and extortion.

Acknowledging the longstanding marginalization of hijras, the supreme courts of Pakistan (2009), Nepal (2011), and India (2014) and the government of Bangladesh (2013) granted legal recognition to hijras as a third gender. Such decisions have led to various types of official acknowledgment, including the addition of a third-gender category on Indian voting lists, Nepali census forms, Pakistani national identification cards, and Bangladeshi and Nepali passports.

Although the legal recognition of hijras as a third gender has been acclaimed in South Asia and internationally as a positive step forward, the change has also been criticized for imposing a singular status on hijras and contributing to misunderstandings about them. The latter issue is particularly the case in Bangladesh, where the state recognizes hijras as a group that is *jouno o lingo protibondhi,* literally "sexually and genitally handicapped." In this way, hijras are erroneously defined as having been born with missing or ambiguous genitals, which reinforces popular local beliefs that hijras have something wrong with them and formally sets them apart from other people, turning their peripheral status into government policy. Moreover, under this framework, hijras who have a penis or undergo emasculation surgery are not "real" hijras, and thus hijra legal recognition in Bangladesh excludes most of the individuals who identity as such and ignores the basis by which they define group membership. This situation forces many hijras to say that they are genitally disabled to qualify for legal and economic rights that would otherwise be denied to them. Elsewhere in South Asia, some hijras today are indicating that they are transgender, as this identity is more intelligible to others because of the effects of globalization.

Hirschfeld, Magnus

Magnus Hirschfeld (1868–1935) was a pioneering sexologist, sexual rights activist, and clinician. A champion of the normalization of same-sex love, he established the first scientific and political advocacy coalitions to repeal anti-same-sex love legislation in Germany. The reach of his scientific research and advocacy was extensive, and his theories gained rapid influence and renown. His indefatigable efforts to depathologize same-sex love on the basis of its naturalness and innateness made him the target of brutal antisemitic attacks. He founded the first international sexual science institute. His theory of sexual intermediaries, which posits sexuality and gender expression on a continuum between absolute male and female, was a theoretical precursor to nonbinary gender identity.

Born in Kolberg, Germany, the site of present-day Kołobrzeg, Poland, into an Ashkenazi Jewish family, established in Pomerania for several generations, Hirschfeld completed his medical studies in Germany and established a practice in Berlin in 1896 with a naturopathic focus. A prolific researcher and writer, authoring more than 500 publications, he led a steadfast and rigorous campaign to decriminalize homosexuality, destigmatize non-heterosexual sexuality, and expand women's rights. In 1896, shortly following the highly publicized trials of the celebrated playwright and novelist Oscar Wilde, a homosexual, Hirschfeld published *Sappho and Sokrates,* a pamphlet that maintained the ubiquity and noncriminal nature of homosexuality.

The following year, he cofounded the Sexual Humanitarian Committee (SHC) to abolish Paragraph 175, the anti-homosexual article, from the German penal code. Under Paragraph 175, male same-sex acts were treated as punishable crimes subject to a prison sentence of 1 year or longer. Same-sex sexuality was deemed a pathological defect that, if left unaddressed, would destabilize the social order, tarnish national values including the reigning normative ideals of masculinity, and threaten to further the spread of degeneracy.

In his campaign for sexual reform, he adopted a tripartite strategy. Deploying scientific research, legal arguments, and an educative platform, he built coalitions with prominent socialists and brought influential politicians and lawmakers to his cause, even garnering the support of key Social Democratic figures such as August Bebel as signatories to his petitions to repeal Paragraph 175. He was the first sexual researcher to formally study the phenomenon of trans men and women, coining the term *transvestitism,* and in 1910 published the first scientific investigation of it, titled *Transvestitism*. He also lobbied for women's suffrage and joined leading German socialist feminists such as Helene Stocker in the fight to legalize abortion, which was outlawed by Section 218 of the German constitution.

Aware that his struggle could not simply be waged on a philosophical and moralistic level, Hirschfeld adopted science as his primary vehicle for legitimizing all sexual identities. Embracing the motto *per scientiam ad justitiam* ("justice through science"), he countered mainstream theories of homosexuality of the time, which maintained that homosexuality was pathological, and posited biological theories to argue that it was a natural and common occurrence that could appear in all segments of society.

Capitalizing on the more liberal government of the Weimar Republic, established at the conclusion of World War I and the defeat of Imperial Germany, Hirschfeld founded the Institute for Sexual Sciences in 1919. The institute served as a research center, sexual clinic, and cultural hub that offered instruction, sexual counseling, and lectures regarding all aspects of sexuality, drawing on the collaboration of prominent international sexologists. Its library housed a vast collection of photographs and over 20,000 volumes on the topic of human sexuality. 1n 1928, he established the World League for Sexual Reform with sexologists August Forel and Havelock Ellis. As a German Jew waging a war on homophobia and anti-homosexual legislation at the height of the highly masculine-coded Wilhelmine empire, Hirschfeld was a frequent target of antisemitic attacks.

Hirschfeld also served as a medical expert in legal matters in sexual criminal trials. He leveraged his influence to combat the suicide epidemic in what was then referred to as the homosexual community, which had resulted from a thriving market for blackmail caused by the criminalization of same-sex sexuality. By 1914, Hirschfeld reported that of the 10,000 men labeled as homosexual whom he had treated, 3% of them had committed suicide. A central component of his advocacy for reform was sexual education. In 1919, he collaborated with director Richard Oswald in the film *Different Than the Others,* which highlighted the reality of homosexual suicide.

Hirschfeld forged alliances with legal activists such as Kurt Hiller and others to underscore the magnitude of the harm and injustice of anti-homosexual legislation. Paragraph 175, they reasoned, was not only compounding the ignominy of subjecting people who were guilty only of following the dictates of their nature but also sanctioning illegal profiteering over matters concerning people's private lives, as well as subjecting individuals to social death and, frequently, to suicide.

He published the *Jahrbuch für sexuelle Zwischenstufen* (*Yearbook for Sexual Intermediary Stages;* 1899–1923), the first academic journal

dedicated to the topic of sexual studies, and published important multivolume studies on human sexuality.

Hirschfeld's biomedical research and vast clinical experience led him to reject a rigid binary sex system and to recognize individuals as neither fully male nor fully female. Foreshadowing present-day queer theory, he viewed gender identity on a continuum between male and female. This was represented by his theory of sexual intermediaries that saw pure male or female types as constructs.

Hirschfeld's role as a clinician, coupled with his acclaim as a leading scientific expert in the field of sexual science, enabled him to facilitate the everyday life of trans and intersex individuals by implementing his expertise to approve legal licenses for them to crossdress in public, which would otherwise have been prosecutable without a permit. Arguing for the innateness of trans identity, he advocated acceptance of those who believed themselves born in a physical body that did not match their gender identity. He pioneered gender confirmation surgery in his institute and was himself involved in performing at least two surgeries. These experiences added to his already considerable international renown, and his expertise in trans medical treatment found resonance in North America, where he became popularly known as the "Einstein of sex," and in other parts of the world. Hirschfeld's work influenced a number of prominent sexologists, including Harry Benjamin, the German American endocrinologist who oversaw the male-to-female gender confirmation surgery of Christine Jorgensen—one of the first such surgeries performed in the United States.

In 1930, Hirschfeld departed for a world lecture tour, which included travel to India, the Middle East, the Pacific, and North America, recounted in an ethnographic study of sexual mores, published in 1932. Toward the end of his life, Hirschfeld published on the topic of racism and put forth arguments against Nazi racial theory. The rise of Nazism prevented Hirschfeld from ever returning to Germany. Following the ascent to power of Adolf Hitler as chancellor, Hirschfeld's institute was destroyed and the contents of its library burned. Hirschfeld died in exile in 1935 in Nice, France, a few days after watching a newsreel in a Paris cinema showing the destruction of his institute.

History

Although *transgender* is a contemporary term, individuals who identified and often lived their lives as a gender different from their sex assigned at birth have long existed in the United States and throughout the world. The existence of genders beyond the binary in the United States can be traced to before it was a country, as many Indigenous cultures recognized more than two genders. White colonial societies saw birth-assigned sex as immutable and punished what they saw as gender transgressions, and this remained the dominant framework in the country for more than 300 years. Trans people have succeeded in building communities and gaining recognition and rights in more recent decades, but they continue to face oppression from large parts of society.

A Framework for Identifying a Trans History

Writing trans history is complicated by how perceptions of gender vary by time and place and by the ways we bring our own perspectives into considerations of gender in different eras and cultures. In contemplating whether female-assigned people from the past who presented as male might have been individuals whom we would call trans men today, anthropologist Jason Cromwell offers three questions to consider: whether the individuals

indicated that they were men, whether they attempted to modify their bodies to look more traditionally male, and whether they tried to live their lives as men, keeping the knowledge of their female bodies a secret, even if it meant dying rather than seeking necessary medical care. Using this framework, Cromwell argues that jazz musician Billy Tipton would be best categorized as a trans man, since he lived as a man for more than 50 years, kept knowledge of his anatomy from sexual partners by using a prosthetic device, apparently turned down what could have been his big break in the music industry for fear that the additional exposure would out him, and died from a treatable medical condition in 1989 rather than risk disclosure.

Cromwell's questions can apply equally as well to individuals assigned male at birth who presented as female to determine if they were likely trans women. Such instances are significantly less documented in Western cultures, in part because of the difficulty of being read as female before the advent of hormone therapy and permanent hair removal techniques. One well-known example is Jenny Savalette de Lange, a member of Parisian high society who lived as a woman for at least 50 years and who was not discovered to have been assigned male at birth until her death in 1858. She had obtained a new birth certificate that designated her as female and had been engaged to men six times but never married, seemingly to avoid her sex assignment from being discovered.

Cromwell helps us distinguish individuals like Tipton and de Lange, who we would now call trans men and women, respectively, from cis people who presented as a gender other than their sex assignment for economic, social, or sexual reasons but who did not seemingly identify as that other gender. But his questions do not speak to the differences between trans women and men and individuals we now refer to as nonbinary. To make this distinction in regard to historical figures, two other questions can be used: if the individuals continued to present outside of their assigned sex, such as through crossdressing, when it was publicly known that they did so, or if they did so consistently but only in private and thus no one else knew, except perhaps their families. In either case, the important demarcation is that the person did not receive any privilege or benefit from their gender expression other than their own comfort and satisfaction.

Gender in Indigenous Cultures

Cromwell's framework assumes that individuals who might be considered a part of trans history had to hide their gender difference to avoid censure and possible punishment. But some non-Western societies welcomed and had recognized roles for individuals who assumed behaviors and identities different from their sex assigned at birth. Many Indigenous cultures in North America at the time of European conquest enabled male-assigned individuals and, to a lesser extent, female-assigned individuals to dress, work, and live, either partially or completely, as a different gender.

Within most of these Indigenous cultures, male- and female-assigned individuals who assumed different genders were not considered women or men; rather, they constituted separate genders that combined female and male elements. This fact is reflected in the words that Indigenous societies developed to describe multiple genders. For example, the terms for male-assigned individuals who took on female roles used by the Cheyenne (*heemaneh*), the Ojibwa (*agokwa*), and the Yuki (*i-wa-musp*) translate as "half men, half women" or "men-women." Similarly, the Zuni called a female-assigned individual who took on male roles a *katsotse,* or "boy-girl."

Some Indigenous cultures apparently considered these individuals to possess supernatural powers and afforded them special ceremonial roles; in other cultures, they were less revered and viewed more secularly. In these societies, the status of individuals who assumed different genders seems to have reflected their gender role rather than a special gender status. If women predominated in particular occupations, such as being healers, shamans, and handcrafters, then male-assigned individuals who took on female roles engaged in the same professions. In a similar way, the female-assigned individuals who took on male roles became hunters and warriors.

A Public Presence in the Dominant Society

The cultural inclusion of individuals who assumed nonbinary genders in many Indigenous North American societies stands in stark contrast to the condemnation of gender nonconformity as

unnatural and sinful in the American colonies in the 17th and 18th centuries. Seemingly because gender-nonconforming individuals faced societal condemnation, many hid their gender difference, and relatively few instances of gender nonconformity are documented in the colonial and postcolonial periods. A number of the cases that became known involved female-assigned individuals who were discovered to be living as men only when their bodies were examined following an injury or death, like Billy Tipton in later times. Many male-assigned individuals seemingly had less ability to present effectively in public as female because of their facial hair and physiques, so likely did so mostly in private.

The lack of a public presence for individuals who assumed different genders began to change in the mid-19th century as a growing number of single people left their communities of origin to earn a living, gain greater freedom, or simply see the world. Able to take advantage of the anonymity afforded by new surroundings, these migrants had greater opportunities to fashion their own lives, which included presenting as a gender different from the one assigned to them at birth. Some headed out West, where crossdressers were a part of life on the frontier. Others moved between small towns or from rural to urban areas, which enabled them to meet and socialize with others like themselves.

In large cities, individuals who would be referred to today as gay men, trans women, and female-presenting crossdressers began to organize public drag balls in the late 19th century. These balls grew to include hundreds and sometimes thousands of Black and white participants and spectators by the late 1920s and early 1930s in cities such as New York, Chicago, New Orleans, Baltimore, and Philadelphia. Organizers would typically obtain a license from the police to prevent participants from being arrested for violating ordinances against crossdressing.

Sexology Considers Gender Nonconformity

The enactment of laws in many U.S. cities beginning in the 1850s that made it a crime for a person to appear crossdressed in public reflected the increasing visibility of individuals who assumed gender behaviors and identities different from their assigned sex, as well as the resulting efforts to contain them. Another indication of the growing presence of such individuals in the late 19th century was the interest that U.S. and European physicians began to show in their experiences. The sexologists, as they came to be known, largely pathologized individuals whom they saw as "gender inverts"—that is, having a gender inverted or opposite of their assigned sex—and did not distinguish them from individuals who pursued same-sex sexual relationships.

German sexologist Magnus Hirschfeld is credited with bringing a more normalizing view of gender nonconformity to the medical literature and for recognizing it as a separate phenomenon from same-sex sexuality in the early 20th century. In his epic 1910 work *Transvestites,* Hirschfeld coined the word *transvestite*—from the Latin *trans* or "across" and *vestis* or "clothing"—to refer to people who presented as a gender different from their sex assignment. In today's nomenclature, his definition included both crossdressers and trans women and men.

The Development of Gender-Affirming Surgeries and Hormone Therapy

Hirschfeld's Institute for Sexual Science, the world's first institute devoted to sexology, also performed the earliest recorded genital transformation surgeries. The first documented case was that of Dora Richter, a female-identified individual who completed her transition with a vaginoplasty in 1931. The institute's most well-known patient was the Dutch painter Lili Elbe. She was also one of its last, as the Nazis destroyed the institute in 1933, holding a public bonfire of its contents.

Although opportunities for surgical transition diminished with the destruction of Hirschfeld's institute, the development of synthetic testosterone and estrogen in the 1930s enabled hormone therapy to become more affordable and, over time, more widely available. The first female-assigned individual known to have taken testosterone for the purpose of transforming his body was the British physician Michael Dillon in 1939. In addition, he underwent more than a dozen operations to construct a penis, beginning in 1946. His were the first recorded female-to-male genital surgeries performed on a non-intersex person.

In 1946, Dillon also published *Self: A Study in Ethics and Endocrinology,* a book that focused on the need for society to understand people who were a gender different from their assigned sex. Dillon was especially critical of the psychologists who believed that they could change the sense of self of gender-nonconforming individuals through therapy, when what their clients really needed was access to hormones and genital surgeries. Making an argument that would become commonplace in the years that followed, Dillon reasoned that since the mind cannot be changed to fit the body, the body should be altered where possible to fit one's gender identity. *Self,* though, was not widely circulated, and Dillon sought to avoid public attention, even going into exile when he was outed by the media.

The Rise of the Concept of Transsexuality

Instead of Dillon, the leading advocate in the 1950s and 1960s for providing hormones and surgeries to gender-nonconforming people became U.S. endocrinologist Harry Benjamin. He began prescribing hormones to them and suggesting surgeons abroad, as no U.S. physician at that time would openly perform gender-affirming operations. Along with U.S. physician David O. Cauldwell, Benjamin referred to those who desired to change their sex as "transsexuals" in order to distinguish them from "transvestites."

While Benjamin raised awareness of transsexuals among medical professionals, it was his patient Christine Jorgensen who educated society. Through the publicity given to her 1952 transition, Jorgensen brought the concept of "sex change" into everyday conversations, served as a role model for many other binary trans individuals to understand themselves and pursue medical treatment, and transformed the debate about the efficacy of providing hormones and gender-affirming surgeries to individuals who identified as a gender different from their assigned sex. Following the media frenzy over Jorgensen's transition, much of the U.S. public began to recognize that "sex change" was indeed possible.

Although hearing about Jorgensen helped many trans women in the United States understand themselves and offered a sense of hope that they too could change their sex, few were able to do so. Most continued to have to travel to other countries for gender-affirming surgery through the mid-1960s. However, this situation changed in 1966, when the Johns Hopkins University opened the first gender identity clinic in the United States to diagnose and treat binary trans individuals and to conduct research related to transsexuality. Similar programs were soon established at other leading universities, and within 10 years, more than 40 university-affiliated gender clinics existed throughout the United States

The sudden proliferation of health care services for trans individuals reflected not only the effect of Benjamin's work and the influence of a prestigious university like Hopkins on other institutions but also the behind-the-scenes involvement of millionaire philanthropist Reed Erickson. A trans man and a patient of Benjamin, Erickson created a foundation that paid for Benjamin's research and helped fund the Hopkins program and other gender identity clinics. The agency also disseminated information related to transsexuality and served as an indispensable resource for the trans community.

The establishment of gender identity clinics at leading universities called attention to the health care needs of binary trans people and helped to legitimize gender-affirming surgery. At the same time, though, the clinics also institutionalized a model of transsexuality that excluded many from the definition of *transsexual* and denied them access to hormones and surgery. To qualify for surgery, someone had to have felt that they were in the "wrong" body from their earliest memories and be attracted to individuals of the same birth sex but as a member of the "other" sex (i.e., be heterosexual after transition). The clinics also expected trans people to conform to stereotypical gender norms, and the likelihood of passing as one's desired sex was a main criterion in gaining access to surgery. Unable to meet these narrow and biased criteria, the vast majority of trans aspirants were turned away from the clinics.

Organizing Among Crossdressers and Drag Queens

The first enduring trans organization in the United States was started by female-presenting heterosexual

crossdressers, or "transvestites," as they were then known. In 1952, a group of crossdressers in Los Angeles led by Virginia Prince quietly created a mimeographed newsletter, *Transvestia: The Journal of the American Society for Equity in Dress*. Although its distribution was limited to a small number of crossdressers and it lasted just two issues, *Transvestia* was apparently the first specifically trans publication in the United States and served as a trial run for wider organizing among crossdressers. In 1960, Prince relaunched *Transvestia* as a bimonthly magazine, and by the mid-1960s, it had more than 1,000 subscribers from across the country. Prince also established an organization for heterosexual crossdressers and their wives and partners in 1961. Known today as the Society for the Second Self, or Tri-Ess, it is the oldest national trans organization.

As the word *crossdresser* slowly replaced *transvestite* as the preferred term among most members of the community, it also began to be applied only to heterosexual men. Gay and bisexual men who presented as female increasingly referred to themselves as drag queens and carved out spaces for themselves in bars, restaurants, and other venues in large cities that catered to (or at least tolerated) them, despite regular police crackdowns. One of the most famous drag queens in the 1950s and 1960s, José Sarria, performed at San Francisco's Black Cat Bar and helped turn it into a social and cultural center for the city's drag community, until harassment from law enforcement and local authorities forced the bar to close.

By the late 1960s, Black drag queens were organizing their own events. Continuing the tradition of drag balls, these more contemporary balls began in Harlem and initially focused on extravagant feminine drag performances. As the balls attracted larger and larger audiences, the competitions became fiercer and more varied, with performers "walking" (competing) in a number of categories. The many individuals seeking to participate in ball culture in the mid-1970s led to the establishment of "houses," groups of Black and Latinx "children" who gathered around a "house mother" or less often a "house father." Given that many of the competitors were youth who had been thrown out of their homes for being gay or trans, the houses provided a surrogate family and a space where they could belong. The ball culture spread to other cities in the 1980s and 1990s and achieved mainstream visibility in 1990 through Jennie Livingston's documentary *Paris Is Burning* and Madonna's megahit song "Vogue."

Trans Power!

The 1969 Stonewall Riots in New York City were not a unique event but the culmination of more than a decade of militant opposition by poor and working-class LGBTQ people in response to discriminatory treatment and police brutality. Much of this resistance took the form of spontaneous, everyday acts of defiance that received little attention at the time, even in LGBTQ communities. For example, historian Susan Stryker recounts two confrontations with the police that, until the 2000s, were largely unknown. One night in May 1959, two Los Angeles police officers went into Cooper Do-nuts—an all-night coffeehouse popular with drag queens and gay male hustlers, many of whom were Black and Latinx—and began harassing and arresting the patrons in drag. The customers responded by fighting back, leading the police to retreat and call in backup. In the melee, the drag queens who had been arrested were able to escape.

A similar incident occurred in San Francisco in 1966 at Compton's Cafeteria—a 24-hour restaurant that, like Cooper's, was frequented by drag queens and male hustlers, many of whom were people of color. According to Stryker, the management called the police one August night, as it had done in the past, to get rid of a group of young drag queens. When a police officer tried to remove one of the queens forcibly, a riot ensued. Vastly outnumbered, the police ran outside to call for reinforcements, only to have the drag queens chase after them, beating the officers with their purses and kicking them with their high heels. The incident served to empower the city's drag community and motivated many to begin to organize for their rights.

Three years later, the Stonewall Riots inspired gender-nonconforming people across the country to activism on an even greater scale. As with the earlier confrontations in Los Angeles and San Francisco, the immediate impetus for the Stonewall uprising was oppression by the local police. But the events that began on June 28, 1969, also

reflected long-simmering anger against anti-LGBTQ discrimination.

The police raided the Stonewall Inn, an unlicensed, multiracial bar, and, as usual, began arresting customers who did not have identification and those who were crossdressed. Unlike in the past, the other patrons did not scatter but instead congregated outside and, with other LGBTQ people from the neighborhood, taunted the police as they tried to place the arrestees into a patrol wagon. As the crowd grew, so did their anger toward the police for their rough treatment of the drag queens and at least one butch lesbian. People began to throw coins at the officers, and when this failed to halt the brutality, they hurled whatever they could find, including bricks from a nearby construction site. Even the arrival of a riot control unit could not immediately quell the uprising. The police eventually succeeded in dispersing the crowd but only for the night. The rioting was similarly violent the following evening—some witnesses say more so—and demonstrations continued for the next several days.

The effects of the Stonewall Riots were both immediate and far-reaching. LGBTQ youth, in particular, felt a sense of empowerment and were unwilling to remain in the closet. At the time of the Stonewall Riots, gay rights group existed at just six U.S. colleges, almost all of which were large universities in the Northeast. By 1971, groups had been formed at hundreds of colleges throughout the country. Reflecting the sense of militancy that had fueled the uprising, many of the new groups called themselves Gay Liberation Fronts (GLFs) and typically had a more radical political agenda than the earlier student organizations. Many of these groups were also initially more welcoming to trans people than the pre-Stonewall groups, and a number of trans people helped form GLFs.

Trans people also established their own organizations in the immediate aftermath of the Stonewall Riots. Sylvia Rivera and Marsha P. Johnson, two trans women of color who had been involved in the riots, founded Street Transvestite Action Revolutionaries (STAR) in New York City in 1970 to support and fight for the rights of the many young trans people who were living on the city's streets. Rivera and Johnson also opened STAR House, a place where the youth could receive shelter, clothing, and food. The house remained open for 2 or 3 years and inspired similar efforts in Chicago, California, and England. Also, in New York City in 1970, Lee Brewster and Bunny Eisenhower founded the Queens Liberation Front and led a campaign that decriminalized crossdressing in New York. Brewster also began *Drag,* one of the first politically oriented trans publications, in 1970.

The Anti-Trans Backlash

Despite the central role of gender-nonconforming people in the Stonewall Riots and their involvement in the political organizing that followed, much of the broader movement soon abandoned them in an effort to appear more acceptable to mainstream society. Six months after the riots, a group comprised mostly of white middle-class gay men formed the Gay Activists Alliance (GAA) in New York City to work solely for gay rights. The group did not consider trans people to be relevant to its mission, and they were discouraged from joining. Similar gay groups that excluded trans people subsequently formed in other cities.

Trans women also faced rejection in the 1970s from some lesbian feminists, who viewed them not as women but as "male infiltrators" and sought to exclude them from "women's spaces." One of the first victims of this prejudice was Beth Elliott, an openly trans lesbian activist who was pushed out of the organization Daughters of Bilitis in 1972 and then forced to leave the 1973 West Coast Lesbian Conference, which she helped to organize, because of hostility from some attendees. Another target was Sandy Stone, a sound engineer who, as part of the all-women Olivia Records, helped create the genre of women's music in the 1970s. Stone had disclosed her transsexuality to the record collective and had its support, but when her gender history became widely known, Olivia was deluged with threats of a boycott and even violence if Stone was not fired. Fearing that they would be put out of business, the collective reluctantly asked Stone to resign, which she did in 1979.

Arguably the most vitriolic and influential attack on trans people was Janice Raymond's *The Transsexual Empire: The Making of the She-Male,* published in 1979 and reissued in 1994. Raymond fomented the witch hunt against Stone

and effectively made trans women pariahs in many lesbian feminist communities. For Raymond, trans women were not women but "castrated" men who were a creation of the medical and psychological specialties that arose in support of gender-affirming surgeries—the "transsexual empire" of her title—to undermine feminism. To thwart this supposed plot, Raymond advocated for a drastic reduction in the availability of gender-affirming surgeries and recommended that trans individuals instead undergo "gender reorientation" (Stryker, 2017, 135).

But far from being a "transsexual empire," the medical establishment largely shared Raymond's prejudices, seeing trans people as needing mental and not physical intervention. Facing an anti-trans backlash, the gender identity clinics performed even fewer surgeries and began to shut down altogether, starting with the Johns Hopkins program in 1979. The following year, the idea that trans people were mentally ill was codified into the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*). Transsexuality continued to be listed as a psychological disorder in subsequent editions, despite the efforts of some trans activists and allies to remove the diagnosis (just as "homosexuality" had been removed previously). The 1994 version of the *DSM* replaced the category "Transsexualism" with "Gender Identity Disorder," but the diagnostic criteria remained largely unchanged. The 2013 edition of the *DSM* helped destigmatize transsexuality by replacing "Gender Identity Disorder" with "Gender Dysphoria," which was described as emotional distress resulting from incongruity between one's gender identity and assigned sex. However, this version still largely pathologizes gender nonconformity among children.

Trans Activism in the Late 20th Century

The 1970s and early 1980s can be considered the contemporary nadir for trans people. However, the period did have a few bright spots. For example, this time marked the beginning of a steady stream of trans autobiographies, including Jan Morris's *Conundrum* (1974), Nancy Hunt's *Mirror Image* (1978), Renée Richards's *Second Serve* (1983), and the first full-length narrative by a trans man published in the United States, Mario Martino's *Emergence* (1977).

More trans people also began to turn to activism at this time to counter the stigma and hostility they experienced. For example, the first trans male support groups were started in the 1970s and early 1980s, including ones in Los Angeles, New York City, and Toronto. The first trans male educational and support organization in the United States, which was called simply "FTM," was begun in San Francisco in 1986 by Lou Sullivan. As the group grew to become the largest trans male organization in the world, it changed its name to FTM International.

The larger trans rights movement also expanded significantly in the 1990s, facilitated by the increasing use of the term *transgender* to encompass all individuals whose gender identity or expression differed from their sex assignment. This understanding became most strongly associated with writer and activist Leslie Feinberg, who called on all people who face discrimination for not conforming to gender norms to organize around their shared oppression in hir 1992 pamphlet *Transgender Liberation: A Movement Whose Time Has Come* and in hir subsequent books, *Transgender Warriors* and *Trans Liberation.* The expansive meaning of the term was further popularized by writers such as Kate Bornstein and Martine Rothblatt, and this usage became commonplace by the late 1990s.

The broad-based political movement that Feinberg envisioned came to fruition in response to continued acts of discrimination and violence against trans people. Reflecting the persistence of anti-trans bias among some lesbian feminists, trans men were often labeled traitors and exiled from the lesbian feminist movement, and trans women were frequently prevented from joining it. Trans women were banned from the National Lesbian Conference in 1991, and a trans woman, Nancy Jean Burkholder, was expelled that same year from the Michigan Womyn's Music Festival. The growth of an out trans community over the course of little more than a decade is demonstrated by the different responses to the expulsions of Stone and Burkholder from lesbian-feminist cultural institutions. While few spoke publicly in Stone's defense in 1979, the ouster of Burkholder in 1991 was widely denounced and led to protests at "Michigan"

itself, with trans activists and allies creating "Camp Trans" across from the entrance to the festival.

It was not only lesbian feminists who discriminated against trans people in the early 1990s. When lesbian and gay leaders were planning to hold a march in Washington in 1993, trans activists and supporters sought to have transgender people added to the title of the event, but the march's national steering committee voted to name it the March on Washington for Lesbian, Gay, and Bi Equal Rights and Liberation. Like their banishment from the Michigan Womyn's Music Festival, their exclusion from the title of the march prompted many trans people to become more politically active and for the trans community to become more organized.

Another major incident that mobilized a large number of trans people was the murder of 21-year-old Brandon Teena in rural Nebraska in 1993. Members of the direct action group Transexual Menace held a vigil outside of the courthouse where one of the murderers was standing trial in 1995. The event was a turning point for trans activism because it was the first highly visible national demonstration organized by trans people and helped draw unprecedented media attention to an anti-trans hate crime.

In addition to Camp Trans and Transexual Menace, a number of other trans institutions and groups were established in the early and mid-1990s. Dallas Denny created the American Educational Gender Information Service (AEGIS) in Decatur, Georgia, in 1990 to disseminate information about trans people. One of the largest annual trans events, the Southern Comfort conference, began in Atlanta in 1991, and the International Conference on Transgender Law and Employment Policy, a yearly meeting to discuss strategies for creating trans-supportive laws, was convened by attorney Phyllis Frye in Houston from 1992 to 1997. In 1995, Riki Wilchins began the Gender Public Advocacy Coalition (GenderPAC), a national organization whose accomplishments included producing the first report on hate crimes against gender-nonconforming people and holding an annual National Gender Lobbying Day to urge members of Congress to address gender-based violence and discrimination.

The 1990s also saw the highly visible, direct-action tactics pioneered by radical groups like ACT-UP (AIDS Coalition to Unleash Power) and Queer Nation begin to infuse the trans movement. The first trans organization to reflect this new queer activism was Transgender Nation, a subgroup of San Francisco's Queer Nation chapter, which was formed in 1992 by Anne Ogborn to fight anti-trans prejudice. Soon, Transgender Nation chapters were established in several other cities. Although it was short-lived, Transgender Nation helped inspire the trans movement to become more visible and confrontational.

But the most significant factor in the development of a national trans movement may have been the rise of the Internet, beginning in the 1990s. Being able to go online enabled many trans people to understand and accept themselves more easily and quickly, connect with others who shared their specific gender identity, and organize trans groups and political actions.

Contemporary Trans Activism and Visibility

The 2000s have witnessed a tremendous increase in trans rights laws and policies, which reflects the successful advocacy of many national trans organizations, including the National Center for Transgender Equality, the Sylvia Rivera Law Project, and the Transgender Law Center. In addition, a number of national LGBTQ and trans-supportive legal organizations have extensively worked on trans issues, including the American Civil Liberties Union (ACLU), GLAAD, the National LGBTQ Task Force, the National Center for Lesbian Rights, and Lambda Legal. These and other groups have called attention to the widespread mistreatment of trans people and have sought to change public perception and the political and legal climate.

One visible response to anti-trans violence and discrimination has been the Transgender Day of Remembrance, an event held every November 20th to memorialize those who have been killed in the past year because of their gender identity or expression. Begun as a candlelight vigil in San Francisco in 1999 to honor Rita Hester, a Black woman murdered in Allston, Massachusetts, the Day of Remembrance is marked around the world today. Reflecting the intersections of racism, misogyny, and transphobia, most of those killed each year are Black and Latinx women.

The 2000s have also seen a dramatic growth in the number of young people who identify as trans and, along with it, a proliferation in how they characterize their gender identities. Whereas trans individuals before the 1990s were largely limited to identifying as a "transsexual" or "crossdresser," those who understand their gender to be different from their assigned sex today have a seemingly limitless number of words with which to describe themselves, fueled by the ability to coin and circulate terms on social media. Much of the new language is used to characterize nonbinary gender identities, including individuals who identify in various ways as genderqueer, gender fluid, and agender.

As the number of individuals who come out as trans or gender nonconforming in various ways continues to grow, it is likely that the crossing and blurring of gender lines will become even more common and accepted. The increasing visibility is also likely to lead to much greater support for trans rights, as many cis people will find that individuals they care about—friends, coworkers, and family members—are trans. In the past two decades, trans activists and allies in the United States have succeeded in advocating for trans-supportive laws and policies in a growing number of states, municipalities, schools, and corporations; the years ahead should see even more progress made toward the recognition and full inclusion of people of all genders.

HIV/STIs

Trans communities have been particularly, and unevenly, affected by human immunodeficiency virus (HIV) and other sexually transmitted infections (STIs). In 2019, the United Nations Joint Programme on HIV/AIDS (UNAIDS) estimated that trans persons are 12 times more likely to be living with HIV than the rest of the population. HIV and STI vulnerability is concentrated among trans people who have sex with cisgender (cis) men, belong to minoritized racial/ethnic groups, live in poverty, and engage in street-based sex work. This reflects intersecting vulnerabilities and resilience factors at the social-structural, sexual network, psychosocial, and biological levels. HIV has had a devasting impact on trans communities globally and, at the same time, has been a mobilizing force. Trans women and other trans people have organized to demand that researchers and programs recognize their unique experiences and needs and to deliver gender-affirming prevention and treatment services.

Epidemiology of HIV and Other STIs in Trans Populations

Trans Women

Needs assessment studies of trans communities conducted in the United States in the 1990s and early 2000s provided initial evidence of the disproportionate burden of HIV faced by trans women who have sex with men. A 2008 meta-analysis of such studies by Jeffrey Herbst and colleagues estimated a pooled laboratory-confirmed HIV prevalence of 28%, with highest prevalence among Black

trans women. The trans health movement leveraged these data to advocate for increased trans-specific HIV and sexual health research, funding, and programming globally. By 2013, when Stefan Baral and colleagues (2013) conducted an international systematic review, they were able to identify 39 studies from 10 middle-income and 5 high-income countries that reported on HIV test results among 11,066 trans women (with most studies limited to trans women who have sex with men). The authors estimated global HIV prevalence to be 19%; trans women had 49 times the odds of HIV infection relative to other reproductive-aged adults. In the United States, an updated meta-analysis published in 2019 by Jeffrey Becasen and colleagues estimated pooled laboratory-confirmed HIV prevalence among trans women of 14%, with findings of individual studies varying widely (1%–41%). This is lower than in previous studies, which may reflect increasing use of more representative samples. Reflecting racial disparities in HIV in the United States, Black and Latina trans women were disproportionately affected, with estimated prevalence of 44% and 26%, respectively. Less research has examined non-HIV STIs among transgender women, but a 2020 global systematic review by Olivia Van Gerwen and colleagues summarized existing data. As with HIV, the prevalence of laboratory-confirmed STIs was high but ranged considerably across study populations (e.g., 1% to 50% for syphilis). In summary, existing data demonstrate a disproportionate burden of HIV and other STIs among trans women but with heterogeneity both within and across countries.

Limitations and Critiques of Epidemiologic Data

The experiences of trans women who have sex with men have often been obscured by their conflation and analytic grouping with "men who have sex with men"; thus, trans-specific epidemiologic data have been critical. At the same time, these data are subject to important limitations. Owing to the historic exclusion and erasure of trans people in HIV data collection, these prevalence estimates largely come from a small number of settings where trans-specific studies have been conducted. For example, in the recent meta-analysis by Becasen and colleagues, 52% of studies were conducted in just four coastal U.S. cities. Sampling bias is also a concern, as many studies have recruited trans women from community venues where trans women living with HIV are likely overrepresented.

Finally, some critical trans studies scholarship has critiqued the imposition of "transgender," as an identity category distinct from sexual orientation, to categorize gender-diverse populations globally for whom that distinction may not apply. As pointed out by Aniruddha Dutta in a 2013 article, this epidemiologic separation of "transgender women" and "men who have sex with men" directly affects communities via HIV funding, which represents a main source of support for trans programs and organizing in the global South. Dutta describes both empowering and marginalizing effects of this globalization of "transgender"; while it provides a framework for much-needed services and advocacy, it can delegitimize identities that challenge cis-trans binaries—primarily held by people of lower-class/caste backgrounds.

Trans Men

Trans men have often been thought to be at relatively low risk for HIV and other STIs, based on the assumption that they have sex with cis women only. In fact, in some studies, a majority of trans men identify as non-heterosexual, and many have sex with men and/or trans women. A systematic review published in 2016 by Sari Reisner and Gabriel Murchison found just 10 studies with laboratory-confirmed HIV prevalence data for trans men (ranging from 0%–4%), all from small studies in high-income countries. In the United States, the 2019 meta-analysis by Becasen and colleagues estimated 3% laboratory-confirmed HIV prevalence among trans men. Racial disparities in HIV are also evident among trans men; in 2016, the U.S. Centers for Disease Control and Prevention estimated that 58% of trans men living with HIV were Black. HIV among trans men in low- and middle-income countries, including those with generalized HIV epidemics, has largely gone unstudied.

People With Nonbinary Gender Identities

Although trans people who identify as nonbinary may have been included as participants in HIV and STI research on trans women and men, there is almost no published research that addresses

their experiences separately. One exception is the 2015 United States Transgender Survey (USTS), which reported data on self-reported HIV status among nonbinary people, finding self-reported HIV prevalence of 1% and 0.2% among nonbinary people assigned male and female at birth, respectively, as compared to 3.4% and 0.3% among trans women and men, respectively (and about 0.3% overall in the United States).

Contributors to High Levels of STIs/HIV Among Trans People

Social structural, sexual network, psychosocial, and biological factors and their interplay contribute to higher levels of HIV and other STIs among trans people. These factors influence prevention and treatment outcomes, as discussed below. At the social-structural level, trans people face stigma, discrimination, and socioeconomic exclusion globally. According to the Human Dignity Trust, in 2019, 73 countries criminalized "same-sex" sexual activity and 15 explicitly criminalized trans identities or gender expressions. Across the world, trans people are denied access to legal gender recognition, education, and employment, with the most severe impacts for trans people who are also marginalized on the basis of race, ethnicity, social class, and other intersecting social positions. Excluded from the formal labor market, trans women in particular often generate income through sex work. There are many types of sex work, and sex workers have varying levels of occupational choice and control over their working conditions. Nevertheless, due to constrained occupational options and stratification within the sex industry, trans women face more unsafe working conditions, including being overrepresented in street-based sex work, where they may have less power to negotiate sexual safety. The criminalization of sex work compounds these risks by increasing exposure to violence and incarceration while reducing access to health services and justice. Anti-transgender and anti–sex work stigma and discrimination are pervasive in health care settings globally and can limit access to HIV/STI prevention information and technologies (e.g., free or low-cost condoms, lubricant, and preexposure prophylaxis), testing, and treatment.

Sexual networks play a key role in determining HIV/STI risk. Scant research exists on cis men who have sex with trans women and on the molecular epidemiology of HIV transmission among trans women. Taken together, this research highlights that trans women are often part of dense sexual networks (interconnected networks facilitate STI spread) involving cis men who may themselves be at greater HIV/STI risk due to their social vulnerabilities and behaviors. While much research focuses on network-related risk, sexual and social networks can also provide protective resources, including sexual health information, emotional support, and health-promoting norms.

At the psychosocial level, trans health scholars have explored how stigma and nonaffirmation of gender identity might contribute to sexual and substance use behaviors that increase HIV/STI risk. Jae Sevelius (2013) argues that trans women of color in the United States have limited access to social and medical gender affirmation yet have increased need for it because of the stigma they face and resulting distress. Therefore, they may engage in behaviors that increase their access to gender affirmation despite health risks, including condomless sex with partners who provide gender validation. Finally, biologically, the risk of acquiring HIV through receptive anal sex is about 18 times higher than through receptive vaginal sex, all other factors being equal. This contributes to greater HIV risk among trans people who have anal sex. It is also possible that hormone therapy and surgeries affect risk for sexually transmitted infections; however, clinical research to answer these questions is in its infancy.

Prevention, Testing, and Treatment

HIV Care Continuum

The HIV care continuum is a model used to describe the progression of people living with HIV from diagnosis through viral suppression. A person has suppressed viral load when there are very few copies of the virus in their blood, often to below the levels detectable by existing viral load tests. People living with HIV who have viral suppression can live healthy lives, with similar life expectancy to people who are HIV negative. In addition, *Undetectable = Untransmittable:* People with an undetectable viral load cannot transmit HIV to their sexual partners. UNAIDS has set targets toward ending the HIV epidemic that involve 90% of people living with HIV knowing their status (being diagnosed), 90%

of those diagnosed receiving antiretroviral treatment, and 90% of those on treatment being virally suppressed. As summarized in a 2019 systematic review by Anna Fontanari and colleagues, trans people are less likely to progress along the HIV care continuum. Stigma and discrimination within health care settings, as well as HIV-related stigma, limit access to HIV testing and to HIV-related medical care. The homelessness and unstable housing disproportionately experienced by trans people negatively affect engagement in care, retention, and adherence to medications. Concerns about antiretroviral (ARV)–hormone drug–drug interactions and side effects of ARVs also contribute to lower levels of sustained ARV treatment among trans women (some ARVs do affect estrogen concentrations, but this can be managed with dose adjustments). Integration of gender-affirming care with HIV prevention and treatment is a key strategy being employed and evaluated to improve HIV care continuum outcomes among trans people.

PrEP

Since its introduction in 2012, preexposure prophylaxis (PrEP; the use of HIV medications by HIV-negative individuals to prevent HIV acquisition) has become a key HIV prevention strategy. PrEP is 92% to 99% effective in preventing HIV infection when taken daily. However, when Madeline Deutsch and colleagues (2015) reanalyzed data from trans women included in iPrEx, a randomized controlled trial of PrEP among "men who have sex with men and transgender women," they found that because of low adherence, the group of trans women assigned to use PrEP did not benefit overall. Subsequent research has confirmed that trans women face multiple barriers to PrEP use and adherence, including a lack of trans-specific PrEP marketing, cost, medical mistrust, and concerns about potential effects of antiretroviral medications on hormone therapy. For trans men and other transmasculine persons, recent U.S. studies indicate that only a small proportion of those eligible for PrEP based on their sexual behaviors had ever received a prescription. Presently, a number of ongoing studies are examining strategies to increase PrEP uptake and adherence among trans women, men, and nonbinary people, including culturally relevant messaging, peer navigation, and integration of PrEP with gender-affirming medical care.

Trans Community Responses

Since the 1980s, trans communities have mobilized to demand inclusion in HIV/STI programs, research, and funding and to organize community-led responses. The success of trans advocacy can be seen in milestones such as the 2015 recognition by the World Health Organization of trans people who have sex with men as a "key population" affected by HIV. At the same time, trans people continue to experience a greater burden of HIV/STI and poorer treatment outcomes. As the global HIV response increasingly turns to biomedical prevention approaches, trans communities are advocating for a robust response to the structural conditions of discrimination, poverty, and criminalization that make trans people vulnerable to STI/HIV and hamper their ability to benefit from advances in HIV prevention and treatment.

Homelessness/Shelters

Trans individuals are thought to be overrepresented in the population of people experiencing homelessness. However, trans people face barriers when attempting to access services and systems meant to assist individuals experiencing homelessness. These barriers range from institutional invisibility and exclusion to individual acts of harassment from staff and service users. The challenges faced by trans people experiencing homelessness are best understood through the lens of cisgenderism. When systems and services are created presuming cisgender (cis) service users, they are unlikely to successfully engage and accommodate trans people. This entry provides an overview of the macro context that contributes to the overrepresentation of trans people in the population of people experiencing homelessness and the challenges they face in accessing shelter services. It also addresses what we know about how many trans people experience homelessness and reviews challenges to shelter access.

Structural Barriers and Systemic Oppression

Before examining the issue of homelessness among trans people, it is crucial to contextualize homelessness among trans people within the larger social context and structural forces that produce and maintain their marginalization, particularly within the housing market and systems serving homeless people. The widespread societal marginalization of trans people can be understood as a product of cisgenderism. Cisgenderism can be understood as the belief system that underlies bias against trans people. This prejudicial ideology neglects the knowledge that all people possess about their gender and also presumes that all people are cisgender. Pervasive cisgenderism affects the lives of trans people in myriad ways.

Social systems often render trans people invisible through policies and practices that assume a cisgender identity. Cisgenderism may manifest in homeless service systems through exclusionary paperwork, a lack of trans-inclusive antidiscrimination policies, misinformed staff, and an overall lack of knowledge regarding trans identities. Cisgenderism and trans bias are so embedded within homelessness services that they have become normalized.

Trans people of color experiencing homelessness not only face barriers rooted in cisgenderism but also are challenged by systemic racism and its effects, such as racial profiling, police and community harassment, and microaggressions. Racism is inextricably linked to housing access and homelessness. For example, the United States is built upon centuries of racist housing policy that has directly affected people of color, particularly Black people, for generations. Consequently, Black people are overrepresented in the population of people experiencing homelessness in the United States. According to the National Alliance to End Homelessness, whereas Black people made up 13.4% of the U.S. population in 2018, they accounted for 40% of the population of people experiencing homelessness. Although people of color and trans people disproportionately experience homelessness and housing instability, homeless service systems are often unable or not equipped to recognize and respond to the needs of people whose lives are negatively affected by oppression rooted in racism, classism, cisgenderism, and trans bias.

Prevalence Rates of Homelessness Among Trans People

Although trans people are thought to be overrepresented in the population of people experiencing

homelessness, it is challenging to estimate exactly how many trans people experience homelessness owing to methodological limitations in enumerating their prevalence. These limitations include the lack of comprehensive response options to questions about gender that would allow trans people to accurately self-identify, discomfort disclosing information about one's gender identity for fear of harassment or service denial, and reliance on administrative-level data to estimate the prevalence of homelessness among trans people, who may not be actively engaged in homeless-serving organizations due to prior experiences of discrimination. Furthermore, the experiences of trans people are often grouped with lesbian, gay, and bisexual people in research on homelessness, making it difficult to determine the percentage of trans people within the aggregated LGBT group data.

Despite these enumeration challenges, it is evident that homelessness is a critical issue for trans people. According to the 2015 United States Transgender Survey (USTS), 30% of the 27,715 respondents reported experiencing homelessness at some point in their lives. Trans adults are estimated to comprise approximately 0.6% of the U.S. population; in studies of homelessness, trans people comprise between 1% and 9% of study samples. The aforementioned methodological challenges contribute to this range, as well as differences in sampling strategies, methodologies, and geographic locations.

Prevalence rates of people experiencing homelessness are monitored in the United States through the annual point-in-time (PIT) count. PIT counts are required for communities that are funded to provide homelessness assistance by the U.S. Department of Housing and Urban Development (HUD). The PIT count provides a census of people experiencing homelessness on one night in January. Based on the 2018 PIT count, trans people made up approximately 1% of the 372,417 individuals experiencing homelessness. Even at an estimated 1% prevalence rate, trans people are overrepresented in the homeless population compared to their representation in the general population. This is likely an underestimate. Because PIT counts predominantly rely on street and shelter-based identification, people who are more hidden, such as those who are couch-surfing or who actively avoid services or for whom it is not safe to disclose their gender, are not reflected in the count. The PIT counts showed a 22% increase in the number of trans people experiencing homelessness from 2017 to 2018, and the increase was primarily of unsheltered individuals.

Several recent studies have examined homelessness among trans youth and young adults. In 2015, the Center for Innovation through Data Intelligence conducted a survey of unstably housed young people in New York City (*n* = 317) in which 9% identified as trans. In Whitbeck and colleagues' 2014 multicity survey of youth street outreach programs (*n* = 656), trans young people comprised 7% of the overall sample. The Homeless Youth Risk and Resiliency Study surveyed 1,427 young adults experiencing homelessness in seven U.S. cities in 2017; 7.5% identified as trans. Although the sample sizes, geographic locations, methods of data collection and prevalence rates of these studies vary, one fact is consistent—namely, that trans people are disproportionately represented in the population of people experiencing homelessness.

Poverty

Examinations of homelessness for any population cannot overlook the role of poverty. Trans people are more likely to be underemployed and to live in poverty and less likely to own homes, all of which make them more vulnerable to homelessness. Employment discrimination undoubtedly contributes to the high poverty rates among trans people: Indeed, their unemployment rate is three times that of the general population. Unemployment and underemployment can make obtaining and maintaining housing nearly impossible for trans people. For trans people who do obtain housing, many also experience discrimination and harassment from landlords and neighbors.

Access to Services

Trans people experiencing homelessness frequently contend with discrimination and violence in their daily lives and encounter systemic barriers and institutional practices that deny their own understanding and articulation of their gender. Despite their increased vulnerability, trans people experiencing homelessness may be less likely to access services meant to transition people out of

homelessness and into stable housing. This is in large part due to pervasive trans bias. Trans bias shapes trans people's interactions with individuals, communities, and systems such that rejection and discrimination become the norm. Therefore, trans people experiencing homelessness constantly navigate an oppressive society that frequently disregards the experiences or denies their very existence. This disregard/denial occurs across a range of settings and is perhaps particularly detrimental when considering the provision of shelter. Some ways that trans bias manifests include binary-gendered bathrooms and sex-segregated facilities, exclusionary paperwork, frequent questioning, misgendering, discrimination, and violence. Navigating binary gendered spaces can result in extreme discomfort for trans individuals, especially nonbinary trans individuals, owing to the frequent failure on the part of programs to respect trans people's self-designated gender within the gendered space.

When considering shelter provision and the engagement of trans people experiencing homelessness with homeless serving systems, it is important to recognize that most, if not all, homeless service systems were created with the cis service user in mind. Consequently, homeless service systems are not designed to accommodate nonbinary genders or anyone whose self-designated gender is different from the gender typically associated with their assigned birth sex. Thus, programmatic policies and procedures may not apply to or include trans people. As a result, trans people face significant barriers to service acquisition and experience negative and sometimes violent interactions when attempting to obtain shelter and supportive services. For instance, when accessing shelter, trans people report harassment, being forced out of the shelter, and/or experiencing physical violence. These negative experiences may lead to trans people leaving shelters due to a lack of safety and mistreatment, even when they have nowhere else to stay.

The inability of homeless service systems to provide safe shelter for trans people has put trans people experiencing homelessness in extreme danger. Trans people, particularly trans women of color, are frequently targets of violence in the United States. The hypervisibility that sometimes accompanies homelessness may further heighten the risk of violence for trans people experiencing homelessness. Recent research documents the violence trans people are subjected to while experiencing homelessness. In Montgomery and colleagues' 2017 study, titled "Gender Differences in Factors Associated With Unsheltered Status and Increased Risk of Premature Mortality Among Individuals Experiencing Homelessness," over half of trans respondents ($N = 25{,}481$) reported experiencing a violent attack while homeless, compared with 35% of cisgender men and 40% of cisgender women. Obtaining help from police when experiencing violence is likely not a viable option for trans people experiencing homelessness because of the harassment many trans people, particularly trans people of color, face when interacting with the police.

Discrimination in the shelter system may not only place trans people experiencing homelessness in danger of physical violence but also leaves trans people experiencing homelessness without access to services, driving many to underground economies (such as the sex and/or drug trades) as a way to obtain basic necessities. Multiple negative outcomes are associated with engagement in the sex trade, such as violence and victimization, HIV transmission, increased risk of suicidality, and potential involvement in the criminal legal system. Mirroring racial disparities identified elsewhere in relation to homelessness, Black trans individuals were found to be four times more likely to engage in the sex trade than their white counterparts. Although negative outcomes related to the sex trade are frequently the focus of research, it is also important to note that some individuals may experience involvement in the sex trade as an empowering choice toward financial stability and therefore may not conceptualize their work as entirely negative.

Transforming Homeless Service Systems for Universal Access

To transform homeless service systems so that all people have access to social support and services, change needs to occur on all levels. In addition to individual interventions, which tend to be the focus of homeless services, interventions must also occur at the structural level. For instance, while educating shelter staff on ways to provide affirming care for trans people experiencing homelessness may

increase shelter access for this population, addressing the structural causes of marginalization and systematic erasure experienced by trans people may actually alleviate the need for shelter access in the first place. Solutions to homelessness among trans people must also include strategies for dismantling cisgenderism and racism, addressing the resulting economic and health disparities experienced by trans people, and creating equitable access to employment, education, and housing.

Hormones, Adults

Gender affirmation for many transgender and gender-diverse (trans) individuals is a multidimensional process involving aspects of social, emotional, and physical affirmation in an effort to reduce gender dysphoria. Gender dysphoria refers to the range of emotional distress experienced when there is misalignment of one's physical body and perceived gender with the internal sense of self. Often the desire for physical affirmation—changing one's outward appearance to be more in line with this internal sense of self—can supersede other aspects of affirmation. Gender-affirming hormone therapy (GAHT) refers to sex steroids administered in various forms to produce or enhance secondary sex characteristics that promote physical affirmation. Using GAHT can reduce the internal stress of gender dysphoria and may also allow some people to move more easily or safely through the world as their affirmed and authentic self. As such, for many individuals, access to GAHT is an important and necessary part of their process.

Medical Gender Affirmation

The goal of GAHT is to create the internal hormone environment that best aligns with a person's gender identity, with the aim of achieving physical characteristics that are culturally accepted and expected as a presentation of that gender. This

often entails taking hormone medications that are affirming, as well as suppressing the body's production of hormones that do not align with one's gender identity. GAHT therapy, most often focused on increasing or decreasing estrogen and testosterone with various medication options, can produce a combination of reversible and permanent changes to the body. Not all trans individuals will seek hormonal therapy as part of their affirmation. There is a great diversity of gender identities and expressions, and providers must assess each individual's goal for accessing care in a nonjudgmental and supportive way. According to the 2015 U.S. Transgender Survey, 78% of all trans respondents desired hormone therapy as part of their gender affirmation (which corresponded to 95% of trans men and women respondents and 49% of nonbinary respondents). GAHT is associated with improved health outcomes overall, and therefore, low-barrier access to medically supported gender-affirming care is strongly recommended.

Hormone Therapy

For many individuals, the aim of starting on hormones is to achieve maximal changes to the body that are culturally read as masculine or feminine. However, some people with nonbinary or genderqueer identities may desire a nuanced hormone makeup to achieve a more androgynous appearance to decrease gender dysphoria. Understanding patients' goals prior to starting on hormone therapy can ensure proper expectation setting and allow for individualized treatment regimens to achieve desired goals whenever possible and safe. Hormones can affect external appearance, leading to secondary sex characteristics of the affirmed gender—for example, testosterone can cause a deeper voice and facial hair growth, whereas estrogen may lead to breast development. Additionally, GAHT can lead to affirming changes in body function by suppressing hormones produced by the body, for example, cessation of menses with testosterone or decreased spontaneous erections with estrogen. Unfortunately, hormones do have their limitations. In individuals who have already gone through their natal puberty, hormones cannot alter bone structure, height, and some other changes that have occurred over time as a result of their born puberty.

In rejecting the rigid concepts of binary identities, many leaders in the field are moving away from classifying hormones into "masculinizing" and "feminizing" hormone therapy but rather referring to the hormones as they are—testosterone, estrogen, androgen blocker therapy—and their known physical effects. In this way, providers can be specific about the effects of the hormones without tying a specific trait or body characteristic to a gender.

Informed Consent

Quite often, individual practitioners and institutions develop their own protocols for evaluation of appropriateness for initiating hormone therapy; however, the most commonly adapted and referenced recommendations come from WPATH (World Professional Association for Transgender Health). WPATH recommends an informed consent approach for assessment and education prior to starting GAHT. The informed consent process can be performed by either a medical or mental health provider experienced in transgender health or, in some cases, by both.

Informed consent refers to the conversation between a provider and patient carefully reviewing a thorough explanation of the benefits, risks, a full list of treatment options, and realistic expectations. It also includes the process of assessing the patient's capacity to understand this explanation. There is not one structured or prescribed way to provide informed consent, but rather it should be individualized to a patient's cognitive and emotional needs, age, and cultural context. It is critical that patients are presented with clear expectation setting—including unknowns due to gaps in research, limitations of medications, long-term health outcomes of therapy—and given space for discussion as to how these align with their goals and expectations for the present and future, for as much as that can be foreseeable. Throughout this process, the individual's sense of self and agency should be promoted and supported.

Testosterone Therapy

Testosterone is the standard medication used to achieve certain changes to the body that some people find affirming, including lowering the pitch

of the voice, increased facial and body hair, fat redistribution from the hips and buttocks to the abdomen, and increased muscle mass. Testosterone can also suppress the body's production of estrogen, one effect of this being the cessation of menses in many individuals. There are several options for administration of testosterone, including injectable formulations, topical gels or patches, and implantable long-acting pellets. There are also oral formulations of testosterone, but these are not recommended for gender-affirming care owing to their negative impact on the liver and the existence of safer options. Choosing which formulation is best often depends on patient preference, ability to self-inject, risks of medication transfer to others if using topical gels, response to hormone therapy, and insurance coverage and cost.

Injectable testosterone is the most common form due to its low cost and excellent ability to increase testosterone in the body quickly and efficiently. Testosterone is typically injected weekly or biweekly and can be injected subcutaneously (SC) or intramuscularly (IM). Data have shown that SC and IM injections provide similar results at the same doses. Biweekly dosing leads to wider fluctuations in testosterone levels between injections, making weekly dosing a better choice for those preferring to keep their hormone levels more consistent from dose to dose.

Topical testosterone is dosed daily and therefore provides consistent serum (blood) levels. Topical formulations are ideal if there are concerns about the effects of significant fluctuations in hormone levels or if more gradual changes are desired. Patients must use caution in avoiding skin-to-skin contact at application area(s) with partners, children, or pets until the medication is completely absorbed, which can take up to 4 to 6 hours.

Finally, long-acting formulations are useful for those who find injections difficult and who are not candidates for topical formulations. These come in injectable forms and implantable pellets and may provide more consistent levels of testosterone over longer periods of time. They tend to be higher cost and need to be administered by a medical professional in the clinic.

Testosterone has been shown to be relatively safe. It can negatively affect cholesterol and potentially increase the risk of high blood pressure but has not been proven to increase rates of cardiovascular events (heart attacks, strokes, or blood clots), at least in the studies published to date. Additionally, testosterone does not appear to increase rates of breast, endometrial, or ovarian cancer. Finally, testosterone may affect fertility, and it is recommended to discuss reproductive goals prior to starting on GAHT therapy, and over the course of time, as family planning desires may change.

Additional/Alternative Hormone Therapy

Some transmasculine or nonbinary individuals may desire additional medications to reduce symptoms of dysphoria. For example, cessation of menses may be critical to gender affirmation, but testosterone and its effects may not be desired. In these cases, hormonal medications—those in the contraceptive class—can be used to reduce or stop menstrual bleeding. Additionally, these medications may also be used as birth control when requested and warranted, as testosterone itself does not reliably prevent pregnancy.

Estrogen and Antiandrogen Therapy

Estrogen can result in certain changes to the body such as softening of the skin, decreased muscle mass, breast growth, slowing of androgenic hair loss, and fat redistribution to the hips and buttocks that some individuals find affirming. Estrogen can suppress testosterone and its effects, but estrogen alone may not be enough to suppress testosterone sufficiently for some individuals. Androgen blockers—or antiandrogen therapy—are medications that can further suppress the body's production or response to testosterone and allow the effects of estrogen to be more apparent.

Estradiol

17β-Estradiol, more commonly known as estradiol, is the recommended medication for GAHT, as this is the bioidentical form of estrogen and observed to have the lowest risk profile, while also being quite effective. Much like testosterone, there are several options for administration, and the choice is typically based on patient preference, accessibility, effectiveness, cost, and safety.

In many studies on overall health outcomes, estradiol does appear relatively safe; however, it has been associated with increased cardiovascular and thromboembolic risk (blood clots, stroke) for those with certain underlying risks factors, such as older age, smoking, elevated cholesterol, hypertension, or diabetes. Estradiol may also increase the risk of breast cancer to slightly higher than that seen in cisgender men, but the rates are much lower than seen in cisgender women. Finally, fertility may also be affected, and discussion of reproductive goals should be discussed prior to starting on GAHT.

Oral estradiol is dosed daily and therefore provides steady levels of estrogen in the body. This formulation is relatively cheap, accessible, and easy to administer. Topical estradiol—in the form of patches or gels—appears to be the safest formulation from a cardiovascular standpoint, showing little impact on lipids (cholesterol) and decreased risk of thromboembolic events when compared to other formulations. This makes topical formulations ideal for those with higher than average cardiovascular risk. Topical formulations are dosed twice weekly or weekly depending on the brand. Finally, injectable estradiol is typically dosed IM every 2 weeks, although dosing weekly with smaller amounts is possible, with the goal of decreasing hormone fluctuations between doses.

Antiandrogens

The most common antiandrogen used in the United States is spironolactone, which is a type of blood pressure medication called a potassium-sparing diuretic. At high doses, it appears to directly inhibit testosterone production, as well as block its binding to the testosterone receptor; it may also exert a small estrogenic effect of its own. It is inexpensive and generally well tolerated.

Over the past 2 to 3 years, some have challenged the safety and effectiveness of spironolactone; however, as of 2020, none of these concerns have been explored at length or proven clinically significant. Currently, spironolactone remains one of the most studied, affordable, and safest options available for gender-affirming care. As additional medications are evaluated for their effectiveness and safety in the context of gender-affirming care, these recommendations may change and more desirable alternatives for testosterone suppression may become clearer. At the current time, however, spironolactone remains the antiandrogen of choice in the United States.

As mentioned above, there are individuals who are able to achieve testosterone suppression without an antiandrogen—either with estrogen alone or if they have undergone a bilateral gonadectomy (the surgical removal of both testicles). In these cases, no additional medication would be indicated for suppression of the body's own production of testosterone.

Progesterone

The benefit of progestins for gender affirmation is not yet well established. Progesterone is typically a part of a cisgender female's hormonal makeup, and therefore it may be desired as part of medical gender affirmation on this basis. Additionally, some patients and medical providers advocate that progesterone may help improve breast development and promote improvements in mood and libido. Progesterone has also proven beneficial in suppressing testosterone, acting as another or alternative antiandrogen. However, common side effects of progesterone are weight gain, fatigue, irritability, and potential increases in cardiovascular risks. It is important to weigh the benefits versus potential risks of starting progesterone therapy on an individual basis. Micronized progesterone is the bioidentical formulation, and research has shown this to be the safest option in terms of cardiovascular health.

GAHT for Nonbinary/ Genderqueer Individuals

Some nonbinary or genderqueer individuals may desire sex hormone levels in a range midway between the physiologic cisgender male and female ranges or to use gender-affirming hormones for a limited amount of time. As with all individuals, prescribing GAHT and dose decision making should be based on a discussion with the patient. A clear understanding of goals and ensuring realistic expectations are necessary, given the unique and largely unpredictable responses of each individual to hormone therapy.

Microdosing is a term that is sometimes used to describe using low doses or limited doses of testosterone or estrogen to affirm a gender identity. There is not one way to "microdose" but rather it is another example of an individualized approach to prescribing hormone therapy. Doses are often started low and monitored closely by both patient and provider to ensure that therapy continues to affirm identity and that undesired changes do not occur. Preprescription counseling is strongly recommended to discuss that it is not possible to predict which changes may occur with hormone therapy for every individual or how fast they may occur. It is imperative to discuss changes that may be permanent and that it may not be possible to tailor hormone regimens to allow for some changes and not others. Patients should be given the option to stop hormone therapy whenever they feel the medication is no longer affirming or desired. A safe but flexible approach to dosing should be presented during the informed consent process for all patients when initiating hormone therapy.

Hormones, Youth

Gender-affirming hormone therapy consists of using testosterone or estrogen to aid trans (including nonbinary) individuals, who so desire, to develop secondary sexual characteristics more in line with their gender identity. Along with social transition and gender-affirming surgeries, it is one of the medically necessary and potentially lifesaving treatments available for gender dysphoria, and it is the standard care for trans adults and adolescents.

Depending on the age and physical development at time of presentation, youth with gender dysphoria may be candidates for different treatment options. For those presenting prior to the onset of puberty or during childhood, most interventions are of a psychosocial nature and include, but are not limited to, social transition and psychological and family support. For these patients when they begin puberty, and those who present shortly after the onset of puberty or during its early stages, puberty suppression with medications such as gonadotropin-releasing hormone analogs is the most widely used intervention, with the goal of halting the undesired development of secondary sexual characteristics, such as breast growth or body hair. For patients who present later in puberty or once puberty is complete, or for those patients who have received puberty suppression and are considered old enough to make informed decisions about their care, the usual next step is the use of estrogen or testosterone to drive the changes consistent with the patient's gender identity.

The initial prescription of gender-affirming hormone therapy is an important milestone for many trans individuals, regardless of age. Although starting hormones is a decision that should never be taken lightly, their use in younger patients poses specific challenges. The prescriber needs to carefully balance the need to wait for a young patient to develop the necessary psychological

maturity to fully comprehend the consequences of starting therapy with hormones and its associated irreversible changes, on one hand, and the potential harm of delaying this valuable and effective intervention unnecessarily, on the other. Although hormone therapy historically and traditionally has started at the age of 16 years, most experts in the care of trans youth now favor starting hormones earlier, when clearly indicated and desired. Hormone therapy should never be started prior to the onset of puberty in children and adolescents who are otherwise healthy, but there is otherwise no lower age limit. Despite this, hormones are rarely started before the age of 13 years. Because of their partially irreversible effects, hormone therapy requires the consent of parents or legal guardians for those under the age of legal decision making (18 years in most states in the United States). The specific requirements for parental consent—for example, one versus both parents, or in cases of divorce, or if a parent is incarcerated—are state specific and require thorough knowledge on the part of the prescriber. It is ideal for patient and family to be on the same page prior to starting hormone therapy, but when there is disagreement between the youth who wants to start hormones and parents who refuse to provide consent, it is the prescriber's role to advocate for the well-being of the minor patient, and as such, often there is a need to act as an intermediary between minors and their parents, or between parents with dissenting opinions. Although rare, some cases have been settled in court, but the outcome of these cases is mixed and dependent on jurisdiction.

Another consideration prior to starting hormone therapy in youth is whether or not a psychosocial evaluation by a mental health professional needs to be completed prior to the start of hormone therapy. While there are multiple advantages to this thorough evaluation, it (a) may potentially delay treatment due to limited availability of these services, (b) can result in high out-of-pocket costs to families, (c) may not be in the best interest of youth (particularly those who have had negative and potentially harmful experiences with mental health professionals who are not familiar with the care of gender-variant youth or are against a gender-affirming model), and (d) may be perceived as pathologizing a condition that is considered a normal variant (i.e., treating a trans identity as an illness that needs to be ruled out or diagnosed prior to receiving treatment). Existing guidelines tend to favor this approach of having a mental health professional as the "point of entry" to care but also allow for other options to assess the need and patient's readiness to start hormone therapy that may be more available and less expensive, time-consuming, and potentially traumatic. Centers with more experience treating trans youth usually rely on behavioral health interventions as a means to support an important life-changing process for those patients who desire this kind of support and not as a necessary step prior to the start of hormone therapy. Behavioral health is an extremely valuable tool for patients who are still exploring their desire to begin hormone therapy and may be very useful in the management of patients for whom it may be harder to assess their understanding of the consequences of starting hormones (e.g., youth on the autism spectrum or youth with other conditions that may limit their ability to communicate).

It is necessary to have thorough discussions about the expected outcomes and potential risks of gender-affirming hormones prior to their start. While hormones are very safe when used as prescribed and with adequate monitoring, they may increase the risk of some adverse events. For individuals who use estrogen, there is an increased risk of breast cancer (usually lower than for cis female relatives), deep venous thrombosis (the development of a blood clot inside a vein), and gallstones. For those who use testosterone, there is an increased risk of polycythemia (the excessive increase in production of red blood cells), acne, and potentially an increase in the incidence of heart attacks or strokes. These risks are usually greater with older age as well as for those who use tobacco products. Despite these risks, it is widely agreed that the benefits of hormone therapy, for those who need it, greatly outweigh the risks. Absolute contraindications to starting hormones are extremely rare in youth.

The most obvious changes expected from the use of estrogen include breast growth, softer skin, decrease in lean body mass (lower bone mineral density and muscle volume, as well as an increase in body fat percentage), and decrease in testicular size. With testosterone, we expect to

see suppression of menstruation, deepening of the voice, development of facial and body hair, growth of the clitoris, increase in lean body mass, acne, and occasionally what is traditionally known as male-pattern baldness. Another potential effect of hormone therapy is infertility, which requires thorough discussion along with referrals for fertility preservation when desired by the patient.

The onset of puberty with the start of hormone therapy for those patients who received puberty suppression, as well as its initiation in those who already experienced puberty (for whom it is informally described as a second puberty) is a time of fast physical and physiological changes and may be accompanied by some psychological and behavioral challenges. Patients may experience mood swings as well as new or worsening depression or anxiety. Often, however, the initiation of hormone therapy may also provide significant relief of gender dysphoria and coexisting psychiatric conditions. In either case, it is important that patients are managed in a holistic and caring manner, and it is the medical and behavioral team's duty to learn about existing patient and family community resources and, if these are not available, to advocate for their creation.

Housing

Trans people face significant barriers to accessing housing, including economic instability and discrimination in accessing rental housing, in purchasing homes, and in accessing credit. These factors result in a higher incidence of homelessness, negative outcomes associated with housing instability, and greater difficulty accumulating wealth—a protective factor against cyclical poverty—compared to their peers. Housing instability can take on multiple forms, up to and including homelessness. For example, nearly 1 in 10 respondents to the 2015 U.S. Transgender Survey (USTS) reported their current living situation to be a temporary arrangement with friends or family because of an inability to independently afford housing. This entry reviews available evidence of housing (in)stability among trans populations and interactions with the housing market, provides a landscape of the civil rights remedies available to address discrimination, and discusses the need for a comprehensive policy and programmatic response beyond nondiscrimination law.

Housing Discrimination

According to the 2015 USTS, nearly one quarter (23%) of respondents experienced some form of housing discrimination in the year prior to the survey, such as being evicted from their home or denied a home or apartment because of their transgender status. Rates of discrimination are particularly high among people with multiple marginalized identities, such as trans people of color. For example, among trans women respondents, 10% of American Indian, 10% of Asian, 11% of Latina, 15% of multiracial, and 17% of Black women reported being denied a home or apartment in the year prior to the survey because of their transgender status, compared to 6% of white trans women. Additional research is needed to examine housing instability among other subgroups of trans people, including trans people with disabilities and trans older adults, whose living situations might include long-term care facilities or other communal settings.

Rental Markets

Data from the 19 states and the territory of Guam who collected gender identity data in the 2014 Behavioral Risk Factor Surveillance System (BRFSS), a federal survey administered by state departments of health, indicate that approximately 30% of trans people residing in those localities rent a home. The 2015 USTS reported that 44% of trans respondents were renting at the time of the survey.

Rental unit testing studies conducted across the United States indicate that LGBTQ people are less likely to receive responses to inquiries about housing availability and, when speaking with housing agents, are told about fewer units and are quoted higher yearly rental costs. A similar pattern appears in research using trans populations. A study using matched pairs of renters published by the Urban Institute in 2017 showed that trans testers were told about fewer rentals compared with cisgender (cis) testers and that trans testers who disclosed their gender identity were less likely than cisgender testers to be told about available rentals.

Home Ownership

Data on homeownership among LGBTQ populations are sparse. Data from the 2015 USTS indicate that relatively few trans people own their own home, with trans respondents being nearly four times less likely to own a home compared with the general U.S. population (16% vs. 63%, respectively). An analysis of 2014 BRFSS data showed no difference between trans and cis respondents on home ownership status in the states with available data (65% vs. 70%, respectively). These mixed findings could be explained by the nature of the survey methodologies used in each study, including that the BRFSS data are only generalizable to the states and one territory that collected gender identity data, showing the need for additional research in this area. A 2018 survey conducted by Community Marketing & Insights for the mortgage loan company Freddie Mac found that 33% of gender-expansive participants reported owning their own home, a lower rate than gay, lesbian, or bisexual participants. In that same survey, 66% of gender-expansive participants who were currently renting a home reported that they probably or definitely wanted to own a home in the future (vs. 68% of bisexual participants, 73% of gay participants, and 74% of lesbian participants). Among that same subgroup, 69% reported a fear of experiencing discrimination during the homebuying process.

Legal Protections and Remedies

High rates of discrimination in housing access may be related to the lack of clear and explicit housing discrimination protections at a national level. The Fair Housing Act (FHA) does not include explicit protections on the basis of sexual orientation and gender identity in housing, although the Biden administration announced in 2021 that it considered LGBTQ people to be covered by the prohibition against sex discrimination in the FHA and other housing laws. As of January 2021, only 28 states and the District of Columbia explicitly prohibit discrimination in housing and homelessness programs on the basis of sexual orientation and gender identity either in state law or under interpretations of existing sex discrimination statutes. The federal Department of Housing and Urban Development (HUD) has accepted complaints of housing discrimination on the basis of sexual orientation and gender identity since 2012 under the legal theory that LGBTQ people are protected under the FHA's protections against discrimination on the basis of sex. HUD issued a subsequent rule in 2016 that gave more clarity about how the protections based on gender identity in the Equal Access Rule should be implemented in its shelters and other housing programs. The Department of Health and Human Services, which oversees grant making under the Runaway and Homeless Youth Act (RHYA), also includes nondiscrimination protections for transgender young people who seek services from these HHS-funded programs. The regulation, issued in December 2016, also includes gender identity and expression under the core competency of "cultural and human diversity," setting out trans-inclusive expectations of workers in these programs. The rule further clarifies that counseling services made available under RHYA do not include conversion therapy or the practice of attempting to change someone's gender identity or gender expression.

It may also be the case that trans people, and LGBTQ people generally, experience discrimination in housing if they use public benefits, like housing vouchers, as a source of income. A 2017 survey from the Center for American Progress found that 14.3% of trans respondents reported that they or a family member had received housing assistance in the year prior to the survey, compared with 2.7% of cis respondents. There is evidence of discrimination against individuals and families who use these benefits, which is why federal legislation to bar discrimination on the basis of source of income has been introduced in the U.S. Congress. In 2020, a review by the Poverty & Race Research Action Council found that 17 states and nearly 100 municipalities have passed some form of source of income protections from discrimination.

Reducing discrimination against LGBTQ people in housing transactions alone may not be adequate to address disparities in housing purchases. In 2019, the National Association of Gay and Lesbian Real Estate Professionals highlighted findings that 70% of LGBTQ renters reported not having money for a down payment as the primary reason for not yet buying a home and that significant proportions of their membership believed that a lack of understanding of home buying and/or the mortgage process, lack of family support, and concerns for being welcomed in new community were factors explaining reduced rates of homeownership among LGBTQ renters. At the same time, research indicates that same-sex couples experience discrimination in credit access and are given less favorable interest rates when they are able to access credit, despite the fact that they are not a higher credit risk than similarly situated different-sex couples. Although studies have not yet been conducted testing the applicability of this finding to single LGBTQ people and nonbinary people, there is no evidence to suggest that the results of such a study would be dissimilar.

Structural Changes to Reduce Housing Instability and Homelessness

Stable housing—and the financial supports to secure stable housing—affords considerable benefits for people who have experienced homelessness, including reductions in psychological distress, substance use, and food insecurity. Protections from discrimination at the federal, state, and local levels are a critical tool for ensuring access to housing and homelessness services for LGBTQ people. It is important, however, to recognize three major drawbacks to a legal protections model.

First, protections from discrimination do little to mitigate the prevalence of housing instability for trans people: Nondiscrimination protections function as a back-end solution, helping to reduce harm for people who have already lost access to stable housing. For example, while a paired-testing study across four states from the Center for American Progress and the Equal Rights Center found that states with LGBTQ-inclusive nondiscrimination laws were twice as likely to be willing to provide a trans women tester with appropriate access to a homeless shelter, the rate of appropriate placement in these states was still only 40%.

Second, legal protection from discrimination within the homelessness continuum of care tends only to be as effective as the implementation and enforcement mechanisms in those laws. Under progressive federal administrations, HUD has invested significant resources into ensuring that the housing continuum of care had the resources and the cultural competency to serve trans people well; it also made clear its intention to enforce the standard of care laid out in its regulations. In contrast, more conservative administrations have taken a hands-off approach to implementation and enforcement of discrimination protections. In practice, this results in stagnation within the continuum of care—providers that prioritize serving trans clients will continue to do so, providers that do not prioritize serving trans people are not pushed to improve their service, and providers that wish to deny service to trans people are not held accountable for those denials.

Finally, legal protections within the housing continuum of care may not provide an effective pathway out of housing instability for trans people. People often experience homelessness as a result of a broader pattern of economic instability, which may be a result of a lack of stable employment, unexpected or compounding health care costs, lack of accessible transportation, involvement with the criminal legal system, an inability to build wealth or access banking services, or any number of other factors. While trans people lack legal protections in and practical access to employment, jury service,

health care, transportation, credit, and other areas, protections within the continuum of care alone will be inadequate to ensure that periods of housing instability and homelessness are an exception and not a norm. Significant funding of prevention programs, undoing intersecting systems of oppression, and addressing drivers to homelessness must be explored more deeply in order to effectively and permanently reduce the number of trans people who experience housing instability and homelessness.

The COVID-19 pandemic that began in 2020 exposed the significant health risks experienced by people who are homeless and highlighted the precariousness of Americans' housing stability. Advocacy for rent freezes and other policy solutions aimed at keeping people in their homes during record unemployment are not likely to prevent a new wave of rising homelessness following the immediate crisis. For the transgender community, members of which already suffer considerable health and economic strain from a long history of marginalization, programs and policies to connect people with such supports are also crucial for long-term health and stability.

ICD

The *International Classification of Diseases* (*ICD,* in full the *International Classification of Diseases and Related Health Problems*) is a diagnostic tool published and periodically revised by the World Health Organization (WHO). *ICD* is the most comprehensive and widely used diagnostic manual, freely available on the Internet, and used for multiple purposes connected with the delivery of health services worldwide. *ICD-11,* the first revision since 1992, was approved by the World Health Assembly (WHA), WHO's governing body, in May 2019.

Many trans people (persons identifying in a gender other than that generally expected on the basis of their birth-assigned sex and therefore experiencing a gender incongruence) seek gender-affirming health care. In most health care systems worldwide, a diagnosis provides a degree of access to those types of health care. Relevant trans diagnoses have been a relatively recent development in *ICD*.

History of Gender Diversity Diagnoses in *ICD*

Early ICD Revisions

Trans-related diagnostic categories were absent from early revisions of *ICD*. *ICD-8* (1965) introduced a diagnostic category called *transvestitism,* classified as a *sexual deviation,* itself in a chapter on *neuroses, personality disorders and other non-psychotic mental disorders*. By 1975, the same chapter in *ICD-9,* in a similarly named section called *sexual deviations and disorders,* had introduced a diagnosis called *transsexualism,* clearly distinguished from a slightly renamed *transvestism* diagnosis. *Transsexualism* itself was divided into several subcategories, according to the sexual orientation of the person being diagnosed (homosexual, heterosexual, asexual, or unspecified).

ICD-10

It was in 1992 with *ICD-10* that WHO recognized that a person's gender incongruence is largely unrelated to sexual orientation or behavior. *ICD-10* created a group of *gender identity disorder* diagnoses, located within a block of diagnoses called *disorders of adult personality and development,* themselves in a chapter on *mental and behavioral disorders*. The key gender identity disorder diagnosis was *transsexualism,* defined as wishing to live and be recognized as being of the "opposite" sex, usually with feelings of discomfort or inappropriateness about one's sexual anatomy, and a desire for hormonal or surgical treatments to change one's body. Other diagnostic categories were *dual role transvestism* (for individuals seeking temporary experiences of being the "opposite sex" without wanting medical treatment) and two residual categories of gender identity disorder (*unspecified* and *other*) for use when the other two categories did not fit. Importantly, *ICD-10* also introduced a diagnostic category for children below puberty (*gender identity disorder of childhood*), this despite the name of the block in which all these diagnoses were located.

ICD-10 remained in use for 27 years. Collaborative research by WHO and the World Psychiatry Association indicated that by 2011, *ICD-10* was used on a daily basis worldwide by more psychiatrists than any other diagnostic manual, including the *Diagnostic and Statistical Manual* (*DSM*) of the American Psychiatric Association. Over these three decades, the social, scientific, and medical understanding of the trans experience grew substantially. Successive revisions of *DSM* to some extent reflected that growing understanding. In 2013, while WHO was engaged in revising *ICD,* the American Psychiatric Association published *DSM-5,* in which the gender identity disorder diagnoses (which pathologized gender incongruence) were replaced with Gender Dysphoria (which rather pathologized the distress and discomfort that might be associated with that incongruence). Meanwhile, *ICD-10* remained largely unchanged, conceptualizing the trans experience as disorder threefold—a gender identity disorder, one of the disorders of adult personality and behavior—in a chapter on mental and behavioral disorders.

ICD-11

ICD-11 was approved by the WHA in May 2019. The revised manual contains substantial changes in the way in which the trans experience is conceptualized. First, the relevant diagnoses are relocated from the mental disorders chapter to a new chapter on conditions related to sexual health (consistent with a broad WHO definition of sexual health). Second, *the gender identity disorders* are renamed as *gender incongruence*—specifically, *gender incongruence of adolescence and adulthood* (GIAA); *gender incongruence of childhood* (GIC), for children below puberty; and *gender incongruence (unspecified),* a residual category. Third, the *gender incongruence* diagnoses are described in a way that explicitly refers to an incongruence between experienced gender and assigned sex and therefore extends to those who identify outside the gender binary. This stands in contrast to the old *ICD-10* diagnosis of *transsexualism* (with its reference to individuals wishing to live and be accepted as "the opposite sex").

A fourth development concerns the GIC diagnosis, for which the diagnostic description makes clear that a child's atypical gendered behavior and preferences are not in themselves sufficient for a diagnosis. A corresponding observation was notably absent from *ICD-10*'s text on *gender identity disorder of childhood*.

Reactions to ICD-11

Clinicians, trans community members, and others have overall celebrated *ICD-11*'s move to "de-psychopathologize" the trans experience (at least for adolescents and adults), to remove the relevant diagnoses from the mental disorders section, and to reclassify gender incongruence as a condition related to sexual health. It is widely thought that this shift can reduce trans stigma and improve access to gender-affirming health care worldwide. There have been lobbying efforts aimed at a similar de-psychopathologization in *DSM*—moves that, if successful, would likely lead to the removal of trans diagnoses from the main text of *DSM* altogether (perhaps with relegation to a section on other conditions that may be a focus of clinical attention).

Reactions to the GIC diagnosis have been more mixed. Although many clinicians and researchers argue that the diagnosis is justified on clinical grounds, others, including trans community organizations worldwide, argue that young children below puberty who are exploring their sense of self, developing an identity, and becoming comfortable expressing that identity should not be regarded as having a medical condition.

Identity Development

People begin life with little awareness of who or what they are and, across a lifetime, develop an internal and stable sense of self through a process called *identity development*. *Identity* is the internal conceptualization that a person has about themselves across a network of characteristics that may include talents, skills, intelligence, and beliefs. Identity can be collective—namely, about one's groups of belonging (e.g., race, religion, class, nationality, and occupation)—and identity can be individual: about oneself. Personal identities may include positive and negative beliefs about oneself, which are influenced by factors such as race, nationality, dis/ability, poverty, nutrition, environmental hazards, trauma, religion, relationships, and sex assigned at birth. A person does not develop *a single* identity but rather develops a constellation of intersecting identities, including gender identity. People whose gender identity, presentation, and/or behavior deviate from the expectations and norms of a society based on their assigned sex may identify as or be labeled trans or gender diverse.

Development of Gender Identity

Identity development is nonlinear, intersectional, and complex. It begins in infancy and continues throughout life and is affected by complex interactions of environment, culture, and biology. Identity frames much of what a person does in life. Gender identity development, like all human development, is influenced by both biology and environment. It is both stable, as well as a continually self-adjusting and dynamic matrix of attitudes, emotions, meaning, expectations, and experiences. The constant and dynamic interaction of person and environment makes it difficult to identify the specific or primary influences, within and external to oneself, on gender identity development.

As trans people develop physically, they begin to interact with their bodies in juxtaposition to what people tell them about bodies similar to and different from their own. Confusion or conflicts in gender identity development arise for the trans individual as they work to integrate differences between what they feel their gender is and what everyone else expects it to be.

Expectations of gender identity development are both overt and implied. Adults tend to refer to others in gendered terms that reflect and reinforce the gender identity expected of people based on known or assumed sex assigned at birth. Children are told repeatedly by people, books, and media how the culture "wants" them to identify their own gender using their bodies as points of reference for gender identity and social roles. By a very young age (usually around 3 years), most children can readily identify and assign the gender categories of man/boy or woman/girl using culturally normative behaviors, clothing, colors, grooming characteristics (e.g., short or long hair, beards), tasks or jobs (e.g., cooking, childcare, firefighter, construction), and vocal pitch, tone, and inflection. Subsequently, children begin to identify inwardly and outwardly with activities and people that they identify as being like themselves. They may begin to emulate the various characteristics and identities they resonate with through make-believe and imaginative play as well as identifying themselves with characters in books and media. They may try on and integrate or reject things that feel most in or out of tune with their developing self-image and gender identity. In this process, trans children may identify with gender roles that are incongruent with their assigned sex and may in turn encounter intolerance and pressure by others to comply with expected gender norms. Expressing a gender identity contrary to social pressure is not always possible for trans people, and many comply with expected gender behaviors and/or repress their internal gender identity to survive.

Physical Influence on Gender Identity Development

Physical and mental development happen both concurrently and separately, are unique to each

individual, and affect gender identity expectations and development. Changes in physical development with the onset of puberty may exacerbate or elicit a sense of misalignment of gender identity with assigned sex for trans children. While physical development may be observed and measured, the emerging dissonance of gender identity development is internal and cannot be observed with the same certainty. Behaviors may provide some insight into gender identity development but are not always aligned with actual identity, owing to social pressures. Social expectations of gender identity development based on sex assigned at birth result in frequent conflicts with differences in behavior expressed by trans people and may lead to altered gender expression or repression of trans identity altogether. While some children who identify as trans in early childhood seem to adopt a cisgender identity later, youth who identify as trans in adolescence appear most often to continue to identify as trans throughout life.

The origin of differences in gender identity development for trans people is unknown. Some theories propose a difference in brain development as one of the crucial factors in developing a transgender identity. Over the past 25 years, there have been just over a dozen studies on the neurological structures and function of trans people's brains. Taken together, these studies are inconclusive. Although they find some differences between trans and cis people's brain structures and function, the cause of such differences, the timing of when in physical development they might arise, and what influence they have on gender identity remain unclear.

Some theories propose that these differences may be intersex conditions, or disorders of sexual development (DSD), that affect only brain development and may interpret these differences to mean that a trans identity is the result of an intersex condition. There are limited data suggesting some connection between differences in sex hormones (androgens) in fetal development and increased occurrence of some trans identities. Very few trans people have DSD conditions, however, and the interconnectedness of DSD with transgender identities remains unclear. The unexplained overlaps and differences between trans and intersex communities do create social contradictions and personal difficulties for individuals who may fall into both categories.

Social Expectations and Gender Norms

People largely *expect* everyone to adopt a gender identity that reflects their assigned sex and the cultural norms. Societies do not generally provide models of gender development outside cisgender identities for trans people to emulate, and each society reacts differently to people who diverge from their gender norms, further isolating and complicating gender identity development for trans people. Trans people are nonetheless found in nearly every culture, although the nature of their experiences and meaning of a transgender identity may vary considerably, as seen in the descriptive language and terms for gender categories since at least the 3rd century C.E. Examples of gender-diverse people appear in Talmudic writings (Jewish), First Nations two-spirit people, and other culturally specific groups such as *hijra* (South Asia), *māhū* (Hawaii), and *travesti* (South America). These examples of gender-diverse people all predate the 20th-century term *trans* yet describe people across cultures and time whose identities are outside their dominant culture's understanding of binary sex and gender identity.

Cultural expectations for gender identity are rooted in a common assumption that genitals equal genetics and equate to immutable and unalterable gender identity. Once a person is assigned a sex, the society exerts unrelenting pressure to re/enforce the associated gender norms on the individual through a mixture of covert and overt rewards, messages, and punishments from family, religion, media, education, and community regarding what behaviors and gender identity are expected. These expectations are reinforced through early childhood socialization and instruction. Socialization of children focuses disproportionately on teaching them gender norms for play, talk, dress, and body movement, which for trans people usually results in learning behaviors that comply with social expectations according to sex assigned at birth while conflicting with their internal gender identity that is incongruent with their assigned sex. There is some indication that a strongly asserted trans identity after puberty (around age 13) in children assigned female, despite conflicts from social pressures to adopt a cis gender identity, may indicate a stable gender identity that will persist and solidify more with age.

Visibility of Internal Gender Identity

Gender identity is the internal sense of oneself as a boy/man, girl/woman, both, no gender, or something else. Internal gender identity may not match what someone shows to the world through gender expression. The social pressure to espouse and express a cis gender identity makes learning someone's internal gender identity tricky. The choice to disclose a trans identity is not always possible or even desirable. Visibility may also change over time, across settings, and with necessity to access resources and supports. Trans people express their gender identity across a range of contexts from blending into cisgender society in their affirmed gender without revealing their history to living visibly as trans whether by choice or not. Greater visibility may be associated with greater identification with the larger trans community, and trans people may individually and collectively use their visibility to press for social changes, acceptance, and to be role models for hope and resilience. Trans visibility may benefit those who are without the language to express their felt discordance; it helps with their realization that they are not unique or alone in their internal experience of gender incongruence to define and solidify their gender identity. Greater visibility as trans may also be the unwelcome outcome of circumstances, may reveal an inability to access gender-affirming care when needed, and may significantly increase a person's experiences of transphobia and violence. Likewise, blending into cisgender society in one's authentic gender may signify fear, provide protection from discrimination and harm, may be a marker of privilege and access to gender-affirming care, or may be the intended culmination of a person's integration and expression of their gender identity.

Transgender Identity Development

There are many gender identity development theories with little consensus. Defining and adopting gender labels, descriptions, and gender expressions are highly specific to the individual, their cultural context, and whatever gender expressions and roles feel most aligned to their internal sense of gender identity. Each subpopulation within the larger trans population (binary, nonbinary, agender, etc.) may go through different developmental processes to reach a consolidated sense of personal gender identity. Some theories focus on the influences of environment and stigma, or adversity, to explain trans identities and expression. Developing a transgender identity, however, is not synonymous with developing gender dysphoria, a mental health diagnosis based on significant distress and functional impairments due to transphobia. Several theories discuss differences in identity development based on gender-affirming medical treatments and/or legal changes. Very few theories address the gender identity development of people who stop or reverse gender-affirming medical treatments (detransition; retransition). What is clear is that there is no agreed-upon normative route in transgender identity development and no single identity across all who identify as trans. A trans person's gender identity develops uniquely without a clear universal starting point or age, with no preset end goal, and with no goal of developing a binary gender identity "opposite" the sex assigned at birth. Most theories of gender identity development have common goals of achieving comfort with, and integration of, a stable gender identity in life, regardless of medical, legal, or social changes.

Awareness of and Hiding Trans Identity

Trans people describe an awareness, at some point in their lives, that how they experience or identify their gender is quite different from what they see in others and from what others expect of them. This may result in anxiety and confusion and lead to inhibition and delays in gender identity development and disclosure. Awareness of difference typically begins in response to family, educators, religious leaders, and community members' reactions to the trans person's expressed gender incongruence. Responses may range from redirection and belief that the person is confused or too young to understand their gender to extreme levels of violence and attempts to forcibly change the trans person's gender identity to cisgender. In response to disapproval, some trans people protect themselves through hiding or suppressing awareness of their gender incongruence. They may work to adopt expressions and behaviors congruent with their sex assigned at birth, trying to feel how they assume cisgender people feel. Some go to binary extremes of social gender norms and may exhibit hypermasculinity or hyperfemininity. These

efforts may not work to suppress the gender incongruence long term, and a person's underlying transgender identity may resurface many years later when it is safe to express.

Trying on Gender Expressions and Roles

Experimenting with gender expressions and roles helps people learn what feels gender congruent and to solidify their internal gender identity. In children or youth, experimenting with gender expressions and role-playing is generally socially accepted as a developmentally typical way youth try on different names, behaviors, identities, and actions to assess fit with their personal identities and interests. By adulthood, however, the trans person may experience resistance and confusion by society about the meaning of deviations from normative gender behavior or appearance, with frequent misinterpretation of gender-variant expressions as indicating non-heterosexual sexual orientation. Trans people may adopt or experiment with a lesbian, gay, or bisexual identity to explore and distinguish their internal sense of gender from sexual identity or to test the tolerance of family and community before disclosing a trans identity. Experimenting with gender expressions that are out of alignment with social expectations may be met with increased pressure to conform and may continue to be confusing or dangerous for the trans person. Trans people may spend years alternating between expressing and then hiding their gender identity or compromising when, where, and how often they express their gender identity outwardly. Gender identity development during this process may appear to take pauses or fluctuate while the trans individual assesses and integrates or rejects different gender expressions and roles based on feelings of internal gender congruence and on external responses from others. During this time, people often begin to become more self-confident about their gender identity and may consider gender-affirming medical treatments to reach a more authentic alignment of gender identity and physical sex characteristics and/or may begin sharing their gender identity more openly with others.

Sharing and/or Affirming Trans Identities

Sharing and/or affirming one's gender identity is important for many trans people as part of their identity development and may also carry risks to safety and health from violence or lack of access to adequate medical care. Trans people may or may not share their gender identities with other people regardless of whether they pursue gender-affirming changes. Gender affirmation includes various measures to bring the physical body and/or social experiences into alignment with the person's gender identity. Physical gender affirmation may require extended periods of time to complete and may be undertaken in stages or in response to the individual's assessment of fit with their identity and while working to gain access to needed resources, treatments, and supports. Social gender affirmation steps may be done privately, publicly, part-time, or full-time and may include legal changes to name, sex designation (M, F, X), and/or government identification documents, when possible (licenses, passport, social security card, birth certificate).

Gender affirmation may or may not be visible to others. For example, name changes remain unknown unless the person shares this information. In addition, around 80% of trans people seek gender-affirming hormone treatments (GAHTs), and some never share this information with anyone, while others experience significant physical changes that require explanation (beard, baldness, voice lowering, breast development), thus forcing disclosure of a trans identity. A motivation for sharing, and an important aspect of affirming and consolidating gender identity, may include asking others to use a chosen name, whether legally changed or not. Being called by a name that aligns with a person's gender identity may improve their mental health and helps with consolidating gender identity as the person is seen and affirmed in their correct gender. Use of a gender-congruent name may also reduce the likelihood of misgendering, lessen internal discomfort, and possibly lower instances of discrimination, helping to stabilize gender identity integration. Trans people may further share and affirm their gender identity through requests for changes in personal pronouns referring to them such as he, her, they, Mr., Ms., or Mx., and they may change use of sex-segregated public spaces such as restrooms, dressing rooms, and locker rooms as their gender identity develops or becomes more visible.

Shared or visible social expressions of gender identity may lead to experiences of conflict for

some trans people, particularly if their affirming gender expressions appear blended, androgynous, fluid, or unclear within the binary gender norms of the society. People who identify as nonbinary, gender fluid, or agender are sometimes labeled as confused or undecided instead of being recognized as having a stable gender identity that blends or rejects social binary expectations. Some trans people may retract what they have shared or alternate starting and stopping gender-affirming expressions or treatments, as they manage internal and external conflicts that may hamper the consolidation and stability of their gender identity (due, for example, to stigma, discrimination, barriers to care, and inhibitions to authentic gender expression).

Consolidation/Integration and Stability of Gender Identity

Consolidation of gender identity is a continuous process that allows for integration of the person's gender with other aspects of their life. Over time, with an ability to express and affirm their internal gender identity, the trans person may reach a reasonable synthesis and stability of their gender identity. Gender identity stability represents a consolidation of the person's internal gender identity with how they want others to see and refer to them (name, pronouns), their gender expression or presentation (clothing, grooming, behaviors), social gender roles (relationships, employment, activities), and with physical self-image and any gender-affirming changes (hormones, surgery). Once integration of physical and social life is stable, some trans people may not share their history of gender affirmation treatment or use the adjective *trans* to describe themselves ever again. Others may become or remain visible by choice or circumstance. Some may be forced by medical needs years later (prostate or ovarian cancer) to disclose their trans identity or history of gender affirmation treatment. A few, to preserve their consolidated identity and avoid discrimination, may forgo intimate contact and/or needed medical care even at the cost of their lives. The ability to reach and maintain a stable and consolidated gender identity requires trans people to be able to clearly communicate their gender identity and to have it consistently be recognized accurately reflected by others. Overall, establishment of a stable gender identity often increases self-confidence, can contribute to increased satisfaction with life and improved relationships, and contributes to improved physical and mental health.

Identity Politics

Identity politics refers to the ways that people who share common experiences, because of their social location(s) in a society, organize to address the inequities they often experience. Typically, this shared identity is a result of experiencing structural oppression. These groups collectively address the politics of inequity and marginalization through activism, research, and/or theorizing.

The concept of identity politics arose from an intersectional framework acknowledging the simultaneous systemic oppression experienced particularly by Black women in the United States. While the term *identity politics* was in use before this, the 1977 Combahee River Collective Statement—analyzing the interlocking oppressions of racism, sexism, economics, and heterosexism—defined and solidified it. Not only did the Collective's articulation address shared structural inequalities, but it also called for the recognition of difference, not as problematic but as an important piece of society, and for individuals and groups to organize, rally for political change, and address the needs of those most marginalized in society.

Individuals hold and enact many identities such as gender, race, ethnicity, Indigeneity, social class, sexuality, (dis)ability, religion, nationality, citizenship, age, and geographic region. Some scholars theorize that specific identities are more salient than others; for instance, the idea that a trans person may experience only or primarily structural cissexism as if their race, sexuality, and/or (dis)ability were somehow separated from experiences of structural privilege and oppression. In contrast, intersectional activists and scholars call attention to the ways individuals and groups experience multiple oppressions while also arguing that normative privileged identities are just as intersectionally salient as marginalized identities. Trans individuals experience structural oppression in relation to their gender identity; however, this is further complicated by their intersecting identities. A white trans woman with financial security would experience structural privilege and oppression differently than a Black trans woman with or without financial security, even though they share a trans identity.

Understanding Identity

One way to think about identities is through three interrelated components. *Personal identity* is how one thinks of themselves, particularly in relation to their social locations in a culture. *Social identity* includes the ways other individuals and institutions attribute an identity to a person, typically based on visual demographic markers. Often, people's personal identities align with their social identities (e.g., someone whose gender identity aligns with their sex assigned at birth). *Collective identity* manifests when individuals with shared characteristics, values, beliefs, and/or experiences group together, often for social change. It is this collectivity based on personal and social identities that shape identity politics.

Many of the identity categories with which people identify, or which others consensually or nonconsensually place them, are based on people's social location in a society. These social locations are culturally defined, and the creation of these social locations, categories, and identities and their associated meanings are often hierarchical and can change over time.

There are three broad theoretical paradigms in understanding identities: essentialism, social constructionism, and social embodiment. *Essentialism* assumes that many identities arise from biological

differences; biology is used to provide distinctions between identities as well as explain differences between the categories within an identity. For example, an essentialist belief is that those assigned male and female are biologically different, resulting in different mental, physical, and social capabilities and capacities, and in a binary-gendered society, these social differences are then rationalized as biologically dichotomous. Those who align with this way of thinking tend to engage in trans exclusionary politics. While a trans person may use medical procedures to change their body, essentialists believe that there is still some biological aspect of sex that is inherent and cannot be changed. Conversely, some trans people have strategically used an essentialist perspective to argue that a person is "born trans." Essentialism has been challenged with research that complicates simple categorizations, particularly into hierarchical binaries.

Social constructionism developed in response to essentialist arguments. In terms of gender, many cultures create distinct identity categories based on heteronormativity, ascribing specific roles and capacities to these genders, and social constructionism understands these as social, not biological, processes. Research repeatedly demonstrates how definitions of man/masculinity and woman/femininity change over time, across cultures, and are not universal. Moreover, Indigenous and global South scholars, among others, point to cultures that have more than two gender categories (e.g., *hijras, travesti, nádleehí, māhū,* and the umbrella term *two-spirit*). This framework has been used by trans people collectively to demonstrate the diversity of genders and challenge binary-gendered societies.

Social embodiment theory is partially in response to essentialism and social constructionism, both of which are viewed as limited. Whereas social embodiment theory challenges essentialism, it highlights the importance of accounting for bodies in theory and research. Social embodiment theory also highlights the flaws of taking social constructionism to the extreme—the idea of taking an individual and constructing a reality, and their identities, for them. If this were the case, trans people would not exist because the gender they were raised as would shape their identity as such. Social embodiment scholars point to the ways in which aspects of sex and/or gender are embodied and do matter, particularly to individual identities. However, they also highlight how societal and cultural definitions linked to particular gender identities shape people's bodies—how individuals learn to walk, sit, speak, and interact depends on their gender and the associated societal norms. This is further complicated by people's intersecting identities, whether normative or not.

Social embodiment theory has been used in trans identity politics to understand two aspects of gender: how trans people may have a strong sense of embodied sex and/or gender that does not align with sex assigned at birth and how understandings of gender expression can take diverse forms. For some trans people, the social identity attributed by others—which is based on the culturally constructed cues to categorize sex/gender—does not fit; even when corrected, some people will continue to ignore trans people's identities. This repeated misgendering, other microaggressions, and the verbal and physical violence that sometimes accompanies it can have a significant negative effect on trans people's well-being. Using procedures to better align their body with their gender identity can help some trans people, and in many cases, the social identity attributed to them is reaffirming. Trans people have often used research in these areas to educate others and push for changes in education policies, social services, and health care.

Boundaries, Borders, and Contestation of Identity

As with all identity politics, while the experiences and other identities among people with a shared identity may be diverse, the strategic use of collective identities requires a defining of that identity—who is included and who is not. The coining of the term *transgender,* as an identity, by trans activists in the 1990s challenged the narrow, medically imposed narrative of what it meant to be transsexual. The institutionalization of *transgender* meant that trans people were now "knowable" as an identity group by the broader society. How trans people have engaged in collective action to bring about change has taken the form of five political organizing strategies. Each of these entails boundary, bordering, and contestation work.

The first organizing strategy is the inclusion of trans within LGBTQ+ identity politics. Especially in the United States, scholars and activists

highlight the importance of gender-diverse people, some who later used the term *transgender,* in spearheading the gay and lesbian movement (e.g., the 1969 Stonewall Riots). These individuals, often at the margins of society because they were poor, houseless, nonwhite, and/or engaged in sex work, did not fit the medical model of transsexuality. For some, this meant they did not have access to legitimate medical means to align their bodies. For others, the goal was to be accepted in expressing diverse genders. The inclusion of *trans* in gay and lesbian identity politics has been contested in a number of ways. Some gays, lesbians, and trans people argue that gender and sexuality are uniquely different from one another and should be addressed separately in identity politics. For these gays and lesbians, trans people were often viewed as a threat to their political agenda, which focused on assimilation politics (e.g., gender normativity and homonormativity). Some trans people also argue that cissexism is different from heterosexism and should be separately addressed. A counterresponse to these perspectives is that LGBTQ+ people share similar marginalization, since sexuality and gender are interconnected, and indeed, many non-Western, global South, and Indigenous conceptualizations of sexuality and gender do not distinguish between the two in the same ways, as is now more common in the United States.

A second type of political organizing is trans-specific identity politics. These groups focus primarily on the needs arising from trans communities and address trans responsibility in advocating for changes. A critique of both trans and LGBTQ+ identity politics is the tendency to prioritize white, middle- and upper-class, masculine, able-bodied, English-speaking, global North experiences and needs.

In response, a third type of organizing focuses on marginalized trans identity politics. Using tools from feminists of color, the experiences and needs of trans people at the further margins of society are centralized. This approach tends to positively affect all trans people in that society.

The fourth type of organizing is the inclusion of trans identities and issues within identity politics not specifically linked to gender. This is often seen within Black and Indigenous LGBTQ+ communities. Activists point to the extreme and shared marginalization people with these identities face across the globe and recognize that a shared intersectional collective identity is stronger and more supportive.

A fifth type of political organizing is actually in the form of *postidentity politics*. This perspective argues that the problem with identity politics is the rigidity and policing of identity categories. They seek, for instance, social change by broadly focusing on gender as an issue that affects everyone. Critics may agree with this assessment for single-identity politics but argue that centering intersectional identity politics addresses structural inequalities by building on the needs of marginalized communities. They also emphasize the importance of coalition building to create broader social change.

Conceptualizing trans broadly as identifying with a gender different from what one was assigned at birth has created a category that allows for a varied representation of trans and gender-diverse individuals within trans identity politics. How identity is used by trans people to challenge cissexist policies and legislation often depends on who is making the claims, who they represent, and what type of social change they seek. For example, successful calls for the inclusion of gender-affirming health care initially used binary gender language but have expanded to include the needs of nonbinary trans people. Ultimately, while trans identity can be used as an organizing political tool, how individuals identify is up to them.

Trans identity politics is complicated in another way. In response to the term *trans, cis* was coined to address normative gender identity—whereby one's gender "aligns" with their assigned sex. This allows scholars and activists to highlight cissexism as unique from, but related to, sexism and heterosexism. While this is an important political strategy, it constructs a border between trans and cis, often excluding those between/within/beyond (e.g., being cis and gender diverse).

Categorization and the Future

The organizing of trans as a unifying collective identity has resulted in a number of legal, political, cultural, and social changes. While these changes have benefited some, often more privileged, trans people, those with intersecting marginalized identities continue to experience

exclusion and structural inequities. The direction and/or strategic use of identity politics is unclear; however, an intersectional and coalition-building approach seems to be more inclusive of those under the trans umbrella, addressing the needs of trans communities, making trans people as a whole more "knowable," and creating social change that benefits a wider number of people within a society.

Immigrants and Immigration

Many LGBTQIA+ immigrants experience forced migration in an attempt to flee violence and oppression in their home country—a process known as *sexual migration*. In the United States, immigrants are migrating regardless of documentation status for opportunities to work, to increase their quality of life, and to experience the freedom to express their sexual orientation and gender identity. Many LGBTQIA+ immigrants, however, confront barriers to health care and employment opportunities in their home countries and in the United States. This includes health care needs for gender-affirming care and knowledge of state and federal workplace protections for LGBTQIA+ immigrants in the United States.

Punitive Immigration Policies in the United States

Introduced in January 2019, Migrant Protection Protocols, also known as *Remain in Mexico,* have affected over 60,000 asylum seekers who are required to remain in México while they await an appointment with U.S. immigration courts. The number of Central American migrants arriving to the United States increased 10-fold from 1980 to 2017 for reasons that include high homicide rates and gang activity as well as climate change and lack of access to basic resources needed to survive. Among LGBTQIA+ migrants specifically, a 2017 study by the United Nations (UN) High Commissioner for Refugees found that 88% were victims of sexual and gender-based violence in their home countries. Furthermore, of those awaiting decisions from the U.S. immigration courts, two thirds suffered violence related to their LGBTQIA+ status in México. Several researchers have documented that many LGBTQIA+ migrants are kidnapped and forced into sexual trafficking during their migration journeys.

Migrants held in U.S. Immigration and Customs Enforcement (ICE) custody also face extreme hardship. As of March 2020, two trans Latinas have died while in ICE detention, and in March 2019, a grievance was submitted to ICE officials by several civil and legal rights organizations for discriminatory treatment faced by a group of 12 gay men and trans women while in ICE detention. Included in this

grievance was a description of ongoing discriminatory treatment directed toward LGBTQIA+ Latinx detainees, including physical and psychological harms from ICE staff and other detainees in ICE custody.

Institutional Roadblocks

For two decades, the United States has recognized LGBTQIA+ persecution as a reason to grant asylum. While seeking asylum is commonly used among LGBTQIA+ migrants, the process itself is idiosyncratic; an applicant must plead their case to authority figures who determine whether the anti-LGBTQIA+ status described by an applicant is a serious and real threat to their lives. U.S. immigration courts ask that a history of sequential, consistent, and coherent persecution be documented by asylum seekers. Documentation is especially challenging for migrants who are fleeing serious persecution related to LGBTQIA+ status, sometimes at the hands of authority figures in their home countries. The easiest method of accessing entry to the United States is via temporary visa programs that allow individuals to visit, study, and work. However, when applying for a temporary visa, individuals must provide evidence of their plans to return home once their visa expires. This process is particularly challenging for many LGBTQIA+ immigrants who migrate to the United States as a means to escape oppression in their home countries. Family and employer sponsorships, the two most popular routes to gaining citizenship in the United States, require documentation of support from one's immediate family or employer.

Global Issues

In Canada, approximately 50% of LGBTQIA+ asylum seekers are successful in obtaining refugee status. This means that another 50% are often sent back to their home country at significant costs to their mental, physical, and economic status. Individuals who are denied asylum may face extreme hardship upon return to their home countries. Canada's asylum process has been critiqued for favoring hegemonic ideals related to gender identity and sexual orientation, thus inadvertently dismissing the rich variability of LGBTQIA+ presentation and experience around the world. For those LGBTQIA+ migrants who successfully obtain refugee status in Canada, many face homophobia and racism that extend from one's family to social service settings.

Outside of the United States and Canada, Belgium is another common destination for LGBTQIA+ asylum seekers. Belgium has become an LGBTQIA+ destination for reasons that include access to national and international adoption for LGBTQIA+ families, some of the most affirming medical services in the world for LGBTQIA+ individuals, and making anti-LGBTQIA+ discrimination a criminal offense. At the same time, Belgium has a long history of conservative social and political values; there is a great divide between the xenophobia, racism, and anti-LGBTQIA+ rhetoric that lies at the heart of everyday life and the laws taken to protect diverse LGBTQIA+ individuals. As such, LGBTQIA+ migrants in Belgium—as in many other countries around the world—continue to face discrimination on a regular basis.

Psychological and Social Health

Trans immigrants worldwide have restricted access to quality, culturally competent health care and mental health services. They are disproportionately at risk for confronting a range of stressors such as physical and sexual violence, persecution by peers and family, and suicide ideation. Understanding the psychological and social health of trans immigrants involves their own unique gender and/or sexual identity development process, as well as factors including acculturation and minority stress as well as personal resilience and perseverance.

Acculturation and Social Isolation

Acculturation for trans immigrants and refugees involves a host of issues, including resettlement, navigating culturally hostile social environments, and other conditions that cause psychological and emotional distress. Race- and gender-based discrimination toward trans immigrants, for example, can complicate and even prevent altogether their search for employment and housing. Further troubling those efforts can be a lack of documentation and legal status.

Acculturative stress over time can fuel a sense of social isolation, some of it related to linguistic challenges and a persistent fear of deportation. For some trans immigrants, efforts to socially integrate into

their environment are met with repeated prejudice and discrimination. Forging and sustaining meaningful relationships with peers and family members is hindered in an unsupportive social milieu and can itself be an additional source of anxiety, which can ultimately discourage care-seeking behavior and access to adequate, timely health care.

Acute Stress and Trauma

Systematic violence and oppression based on xenophobic, anti-trans sentiments are a reality in places such as Latin America, Asia, Africa, and the United States. Researchers have documented cases of pervasive anti-trans verbal insults and bullying beginning in childhood and across settings, including at home and in school. High levels of stress over time from taunting and intimidation by peers, as well as the looming threat of physical and sexual violence, are some of the reasons why trans immigrants are disproportionately affected by the emergence of posttraumatic stress disorder symptomology, including hypervigilance, intrusive thoughts, and frequent incidents of avoidance and panic.

Trans people in general, but particularly trans immigrants, have a disproportionate risk for being victims of violence where the use of violence is considered extreme and cruel when compared to the nature of the motivating crime. In addition, evidence from sworn declaration, psychological evaluations, and life histories of trans immigrants suggests a long history of economic and safety insecurity that is further compounded by a mistrust of law enforcement. Trans immigrants are often repeated victims of abuse and mistreatment from police and immigration officials, which can fuel lifelong battles with severe anxiety, depression, and the use of drugs and alcohol to cope.

Depression, Substance Abuse, and Suicidality

Depression and suicidal tendencies are correlated, and that association strengthens when alcohol and other drugs are involved. Analysis of mental health records has shown that trans immigrants have a disproportionate risk for developing clinical levels of depression characterized by a pervasive sense of sadness, guilt, a loss of focus and motivation, and hopelessness. This cluster of symptoms is more frequently observed among trans immigrants who are undocumented than among those who have already obtained legal residency status.

Trans immigrants, like many other migrants who have minimal access to counseling and other health and social services, rely on alcohol and other drugs in order to cope with their oppressive environmental conditions. The hazardous use of alcohol, in particular, has been found to increase during the period of migration for trans immigrants, which further raises their risk for repeated thoughts of self-harm and suicide. Nonbinary trans immigrants are at greater risk for engaging in hazardous drinking to cope with anxiety and depression.

Resourcefulness and Resilience

Being connected to a network of immigrants in the United States and in other areas around the world can serve for trans immigrants as a buffer against the detrimental effects of ongoing persecution and victimization. Experiencing social support helps trans immigrants moderate the frequency of hazardous drinking and also lowers their risk for experiencing depression and anxiety. Informal relational connections facilitate the help-seeking process as well as the search for housing, work, and transportation. Research in the United States and Latin America also suggests that trans immigrants rely on their social networks to access individuals with whom to speak to process traumatic incidents and histories, as well as to manage current stressors.

In addition to helping trans immigrants feel resilient in the face of adversity, social interactions with other trans immigrants can foster a sense of hope for the future. Trans immigrants, like many LGBTQIA+ people, rely on alternative forms of kinship such as the idea of a "chosen family" as a protective response to pervasive anti-trans sentiments within the birth family. Social interactions essentially help build community, which generates opportunities to ask for and receive help. A sense of community also creates pathways to volunteer and "give back," and this can reinforce a feeling of social belonging and acceptance.

Indigenous People

The term *Indigenous people* refers to descendants of the original or earliest human inhabitants of a territory or land mass (e.g., Indigenous people of North America). Capitalized as a marker of respect, *Indigenous people* refers to a group of Indigenous individuals and is distinct from Indigenous *peoples* (plural), which refers to specific Indigenous groups, communities, or nations. *Indigenous people* is used to distinguish original inhabitants of a territory from those who arrived later, or who occupied, settled, or colonized a territory already claimed by Indigenous people.

Indigenous nations have a long history of asserting their sovereignty, which refers to a group's right and power to govern itself without interference from competing governing powers. Sovereignty is most clearly established in its exercise, even when this status is not recognized by others, and the continued existence, as well as the increase in numbers of Indigenous peoples, is testament to their continued and effective resistance.

Caution should be used when generalizing about Indigenous people, as the category encompasses most cultures or nations that lack a history of colonizing others. There may be significant difference among Indigenous communities or nations, even in a limited geographic region. The U.S. federal government, for example, recognizes 567 Indigenous tribes within its borders as of 2018. The World Bank estimates that Indigenous people make up 5% of the global population. The 2016 Canadian census, for example, identified 4.6% of the population as Indigenous (First Nations, Inuit, or Métis), amounting to 1,673,780 people. The U.S. Census of 2010 estimated that 1.6% of Americans are Indigenous (Native American or Alaskan Native), numbering 5,220,579. This figure does not include Indigenous Hawaiians (Kanaka Maoli) or those in territories claimed by the United States.

This entry provides a brief overview of issues related to Indigenous people and gender and then summarizes how these issues relate to colonial assimilation of Indigenous people and to Indigenous rights. As with all cultures, approaches to gender among Indigenous people vary by community, are shaped by interactions with other gender frameworks, and change over time. The ability of Indigenous people to express their gender, maintain its cultural meanings, and instill gender-related values, practices, or perspectives in subsequent generations is shaped by the impact of historical, current, and ongoing colonialism. As technological

developments facilitate communication on a global scale, the pace of change, including change related to colonial assimilation, may accelerate, with cultural views of gender being shaped by events on a national, international, and global scale.

Indigenous People and Gender

Outside of experiences of colonialism, few factors are held in common by all Indigenous people. Comparing Indigenous models of gender with Western models, a few distinct elements occur among multiple Indigenous peoples:

- *Variation in approaches to gender.* No single model of gender is common or enforced across all Indigenous groups. Some Indigenous languages lack gendered pronouns, such as *he* or *she,* and may place less emphasis on gendering, or exhibit a gender-inclusive perspective. Other Indigenous people may have gender-segregated communities, gender-specific dialects, practices, or roles and acknowledge individuals who shift within a binary.
- *Communal approaches to gender.* Some Indigenous cultures emphasize the group over the individual, viewing human beings as interdependent rather than independent. As a result, gender may carry responsibilities toward the family, community, or nation, rather than be considered a personal or private matter.
- *A spiritual component to gender.* In addition to having psychological, biological, or sociological meanings, Indigenous cultures may consider gender to have its origin in spiritual experiences, and specific gender expressions may come with expectations regarding spiritual practices or ceremonial roles.
- *Multiple gender categories*. Research has found that some Indigenous nations include three, four, five, or more distinct genders. A third gender commonly includes people who mix masculine and feminine traits or perform a mix of gendered social roles. In contrast, binary European frameworks limit gender categories to men and women and may censor expressions of gender that are considered nonconforming. Where multiple gender roles are recognized and incorporated, they are generally not stigmatized.

There is enormous variety across and within Indigenous cultures, and caution should be exercised before assuming that any given Indigenous group recognizes or embraces a given gender expression. Moreover, colonial efforts to control or eliminate specific gender roles may also have negatively affected Indigenous people whose traditions did not hold such views.

Colonial Assimilation

One colonial practice that has significantly damaged Indigenous gender frameworks is the use of forced "schooling" to assimilate Indigenous people into the settler population by eliminating Indigenous language, culture, spirituality, and identity. Colonial governments forcibly confined Indigenous children to "Indian residential schools" in Canada (c. 1884 to 1996) and Australia (c. 1885 to 1984) and "Indian boarding schools" in the United States (c. 1819 to 2007). These facilities forcibly assimilated generations of Indigenous children into settler religion, language, culture, gender, and sexuality.

Many residential schools were operated by Christian religious organizations and asserted that settler cultural views such as a heteronormative binary gender system and practices such as monogamy were divinely ordained. Some Indigenous gender roles and practices, particularly those with Indigenous spiritual significance, were denounced by settler authorities as evil. Some scholars have noted that assimilation programs connected the performance of settler gender roles with economic survival, training Indigenous children to occupy subordinate positions in a gendered capitalist economy. Indigenous girls, for example, were often trained to perform as housemaids for settler families, while Indigenous boys were often trained to work as farmhands.

As a result of generations of forced assimilation, the transmission of Indigenous culture and knowledge was severely interrupted. Language assimilation, such as forcing students to speak only in English, led to a loss of Indigenous language fluency—including vocabulary for describing gender—and endangered the survival of many Indigenous languages altogether. As a result, many Indigenous political, social, or ceremonial roles for third, fourth, or fifth gender people have been lost,

and many Indigenous people grew up knowing only European Christian gender frameworks.

Residential and boarding schools were underfunded and overcrowded. A vulnerability to infectious diseases such as tuberculosis was exacerbated by malnutrition, inadequate heating and sanitation, physical abuse, and exhaustion from overwork. In Canada, where there were fewer schools and more children attending them, some schools reported a death rate as high as 50%. Research by food scholar Ian Mosby has revealed that some Canadian residential schools purposely underfed children and denied them medical care in order to conduct experiments on the effects of malnutrition.

While practices varied between schools and settler colonies, an international pattern is evident in reports of the physical, emotional, mental, and sexual abuse experienced by many Indigenous people forced to attend residential or boarding schools as children. A study in the United States with Indigenous LGBTQIA+ and two-spirit people (i.e., individuals whose gender combines masculine and feminine) forced to attend boarding school found that 34% of children had been physically harmed while there, and 28% had been harmed sexually.

Assimilation practices, such as those in residential and boarding schools, severely affected Indigenous cultures and specifically four aspects of Indigenous gender:

- Variations in approaches to gender were replaced by a binary gender model imported from Europe and built upon Christian doctrines. Distinct gender models, and often the terms used to describe them, fell into disuse by the 1930s, although many have seen a resurgence as part of movements by Indigenous people to make their lives decolonized—devoid of colonial influences—and Indigenized—informed by the values, beliefs, and practices of their Indigenous nation.
- Communal approaches to gender were replaced by individual approaches. As a result, some Indigenous people may experience and describe their gender in the same way as might Europeans and their settler descendants. Some Indigenous people have reclaimed interrelational models of gender or developed hybrid models.
- A spiritual component to gender was replaced by a Christian model that labeled some gender expressions as sinful and others as obligatory. In many settler nations, this was later replaced by a secular model, which substituted cisnormative beliefs about human biology in place of Christian doctrine. The emergence of two-spirit identity was, in part, an attempt by Indigenous LGBTQIA+ people to reclaim a spiritual and ceremonial meaning for their lives.
- Multiple gender categories were replaced by a Western binary system that limited gender to men and women. Even when the binary system was challenged or expanded upon, it often continued to be framed as reflecting a universal (rather than cultural) truth. For this reason, some Indigenous people resist labels such as "trans," even if their experience seems to fit the category, preferring a label such as "two-spirit" or a term from their Indigenous language.

Many countries are now struggling to reconcile their actions against Indigenous people with their contemporary values. Testimony regarding experiences at residential schools in Canada, for example, has been collected by the Truth and Reconciliation Commission (TRC) of Canada. Between 2008 and 2014, TRC representatives collected testimony from 6,500 survivors of residential schools, including a session with Indigenous LGBTQIA+ and two-spirit people. The commission's findings were published in 2015 in a summary report that included 94 "Calls to Action" to redress the wrongs done to Indigenous people by the residential school system. Despite efforts to redress the harms of specific colonial practices, the negative impacts of forced assimilation extend beyond those individuals incarcerated as children by the settler state. Scholars note that negative mental and physical health effects are measurable in the descendants and extended family members of survivors, and research indicates these impacts are transmitted both socially, through maladaptive coping mechanisms, and epigenetically, as experiences shape genetic inheritance and gene function.

Indigenous Rights

In an effort to address historical injustices and prevent such wrongs in the future, a number of organizations and governmental bodies have issued statements regarding the rights of Indigenous

people, either within the borders of specific settler colonial nations or on an international scale. Significant among these is the United Nations Declaration on the Rights of Indigenous People (UNDRIP). The resolution, adopted by the UN General Assembly in 2007, affirmed the human rights of Indigenous people; denounced the racism, discrimination, and injustice to which Indigenous people have been subjected (in many cases by the very nations making the declaration); and affirmed their right to autonomy, self-determination, and self-government.

At least 10 articles in UNDRIP could be interpreted to support Indigenous gender frameworks:

- *Article 5* affirms "the right to maintain and strengthen" distinct Indigenous "political, legal, economic, social and cultural institutions," among which one might count traditional multiple gender roles, and a spiritual component to gender.
- *Article 7* includes a right to "mental integrity," which could be argued to include gender identity.
- *Article 8* declares freedom from forced assimilation or cultural destruction, a clear reference to the history of residential and boarding schools. This article could be seen to affirm the legitimacy of Indigenous gender expressions that differ from those of settler populations.
- *Article 11* asserts "the right to practice and revitalize their cultural traditions and customs," which could apply to all four aspects of Indigenous gender noted above. This same article affirms that Indigenous people have the right to "maintain, protect and develop" their culture, which could include reclaiming traditional gender roles and models or reimagining new ones to reflect contemporary Indigenous values.
- *Article 12* affirms the right to "spiritual and religious traditions, customs and ceremonies," among which valuing a spiritual component to gender fits easily.
- *Article 13* includes a right to use a revitalized Indigenous language, and *Article 14* includes a right to Indigenous language education. Together, these could support preservation and revitalization of terminology related to Indigenous genders and LGBTQIA+ or two-spirit people.
- *Article 25* asserts "the right to maintain and strengthen" a spiritual connection to their territory, which may take distinctive forms for two-spirit and other Indigenous gender minority people.
- *Article 31*, the right "to maintain, control, protect and develop" Indigenous culture and knowledge, could support the reinstatement or revisioning of Indigenous-specific gender frameworks.
- *Article 34,* which relates to promoting, developing, and maintaining "distinctive customs, spirituality, traditions, procedures, practices," could easily be applied to all four gender themes identified above.

UNDRIP is not legally binding under international law, and in this regard, the document is more a statement of aspirations than of contemporary governmental policy. Four members of the UN, Australia, Canada, New Zealand, and the United States, voted against UNDRIP but later endorsed the declaration informally. It has been noted that the opposing member states have large settler-majority and small Indigenous-minority populations.

Informed Consent Model

An *informed consent model* of trans care is an approach to primary medical care. The primary

use of this approach is for gender-affirming hormone treatment; gender-affirming surgeries are not typically included in an informed consent model of care. An informed consent model emphasizes the medical provider–patient collaborative process of evaluation of medical need, treatment options, and discussions on the expected effects and possible risks involved prior to starting any medications. Treatment is then provided based on the patient's ability to understand the treatment risks and benefits (informed) and to legally agree (consent) to be treated. The main feature of this model of care is that it does not require a trans person to receive mental health therapy, get psychological testing, or have a mental health professional write them a referral letter before the person can start gender-affirming medical treatment. An informed consent model of care also incorporates a *harm reduction* approach to treatment, providing gender-affirming care starting where the person's needs are, for example, by providing medical supervision of nonprescribed (e.g., *do-it-yourself, DIY*) hormone treatments without demanding the person stop all hormones first.

An informed consent model arose as an alternative to what is commonly known as the *standard model* of care and in response to the needs and demands of the trans community for greater access to gender-affirming medical care. The standard model of care derives from the international World Professional Association for Transgender Health (WPATH) *Standards of Care for Transsexual, Transgender, and Gender Nonconforming People* (SOC). While the SOC itself is flexible and supports both standard and informed consent models of care, it strongly favors a standard model of care that stresses the involvement of mental health professionals in gender-affirming medical treatment. This emphasis on mental health professional involvement in care underlies the objections to the standard model of care and what many trans people believe to be an underlying pathologizing bias that creates unnecessary and unwanted oversight and control of their lives, thus removing their autonomy. This oversight is called *gatekeeping*. Gatekeeping places mental health professionals in the position of deciding whether and when a trans person can access gender-affirming medical treatment, which has resulted in widespread distrust of mental health professionals by trans communities. Nonetheless, the standard model of care may be preferred by medical providers who seldom receive education in trans health and have limited knowledge or experience with the management of gender-affirming treatment.

An informed consent model stresses that direct work with trans patients increases provider firsthand knowledge and produces more satisfying and effective care outcomes with reduced bias in treatment. Research shows that trans people are more likely to make use of care when that care is easy to access and not based in assumptions that their gender identities are a mental illness because they differ from cultural expectations based on sex assigned at birth. Informed consent–based care is not without challenges. Because an informed consent model does not automatically involve mental health professionals, the model is misunderstood by some people in the trans community to imply getting *hormones on demand,* meaning receiving prescription medications from a medical provider without having any assessment of need and suitability of care options by the medical provider or anyone else. An informed consent model, nevertheless, does involve an assessment of the patient's medical need for and ability to give consent to a specific treatment.

An informed model of care does not eliminate the need for mental health care and support. At times, mental health care may still be a requirement as part of gender-affirming hormone treatment or other gender-affirming medical care. Consequently, while an informed consent model does not automatically require assessment by or psychotherapy with a mental health professional, exceptions to using this model of care exist. These exceptions may include treating individuals who are not legally able to give consent for medical treatment (i.e., minors and those with a guardian) or if the medical provider finds any mental health or medical condition that would suggest the person is unable to fully understand the treatment risks and benefits to consent to care.

Other exceptions and conditions required to access gender-affirming care may exist within an informed consent or standard model of care and can vary by health insurance requirements, medical provider, and availability of and access to trans informed care; by state; and by country. For

example, the SOC contains some recommendations for care that may be skewed toward Western European and North American interpretations and may not exist or be accessible in all cultures and regions. Informed consent models of care tend to be localized and are not uniformly set out in any standardized treatment guideline. All trans care must be interpreted and applied by health care providers with responsiveness to the specific context and needs of the population served.

Thus, while an informed consent model of care seems to be preferred by many trans people, it remains an option for care that may only be available to some trans people based on where they live, their individual situations and needs, and the health care providers to which they have access.

Inmates and Incarceration

Trans communities, especially trans people of color, are incarcerated at higher rates than the rest of the population. By challenging the prison status quo, trans people reveal the gender binary as intrinsic to the modern prison and trans issues as central to critical emerging issues of law and policy, public health, and the social sciences. This entry addresses the ways that trans people uniquely experience "the pangs of imprisonment," the dangers associated with being trans while incarcerated, and the efforts of trans activists to eradicate these harms.

Prisons, which sociologist Erving Goffman called a "total institution," are by design environments of extreme control and deprivation of liberty. When individuals enter prison, they are strip searched, their belongings are confiscated, and they are given an identification number as a unique signifier. They are issued prison uniforms and sundries, subjected to health screenings, and assigned to facilities according to risk and needs, but mostly risk. While incarcerated, prisoners experience physical violence and endure other negative consequences as part of the collateral consequences of imprisonment. For trans people, this is true in ways that are similar to and different from other people who are incarcerated.

Prisons are increasingly recognized for their cissexist assumptions that sex and gender are binary and that they map onto each other in binary ways: for example, that people with male genitalia are men and that men are masculine. The presence of trans women disrupts these assumptions and the routine prison operations that flow from them. During prison intake, when trans prisoners are strip searched, they are routinely mocked for their gender presentations or genitals. Their personal identification is collected and documented in accordance with records that may conflict with their chosen names and their gender expressions. Their belongings are confiscated and replaced with personal effects that do not necessarily align with

their gender identities and expressions. They are issued prison uniforms that defeminize and deidentify. They are subjected to screenings that rely on genitals—not gender—to determine housing assignments. They are assigned to sex-segregated facilities where they disproportionately encounter violence. They are more frequently placed in solitary confinement, where their freedoms are more restricted and their well-being put further at risk. They are consistently denied essential medical care. In sum, trans people differentially experience harm behind prison walls.

The differential harm experienced by trans prisoners can be traced in part to prisons as sex-segregated institutions. Sex segregation in prisons means that prison officials classify and separate individuals on the basis of determinations of sex as either male or female. These determinations typically are based on genital screenings, and they significantly affect life behind bars. Prisoners are assigned to facilities, referred to, and treated according to the sex determined by prison officials, which marginalizes many trans people.

Some correctional facilities have reformed their policies to separate trans people from their general populations. For example, Los Angeles County Men's Central Jail houses trans women and other gender-nonconforming people assigned male at birth in a unit called K6G. To screen for K6G, officials conduct a genital examination and ask a series of questions about gender and sexuality, coming out, and trans culture. For example, trans people may be asked when they came out to friends and family and to provide the names and numbers of those who could verify their gender. This process has been criticized, however, as failing to reduce harm for some of the jail's most vulnerable, including trans women of color who may not fit stereotypes embedded in K6G's screening process.

Trans women face significantly higher rates of prison violence than other prisoners, and trans women of color are the most likely among trans women to be abused. Researchers have found that trans women are more than 13 times more likely to be sexually assaulted. Under this threat of violence, trans prisoners often also carry the emotional pain and attendant psychological trauma of concealing one's gender because they fear transphobic reprisal. Specifically, trans women are recognized as victims of sexual violence at the hands of heterosexual men with whom they serve time in prisons.

A lack of adequate health care compounds the transphobia within prisons. Trans prisoners are often denied access to hormones and other gender-affirming care that, when withheld, is linked to negative mental, physical, and sexual health outcomes. For many trans people, hormone therapy is a medical necessity that reduces substance abuse, depression, anxiety, and suicide. Moreover, sudden discontinuation of hormone therapy can be life-threatening. By denying trans people necessary medical care and appropriate treatment, prisons are increasingly found to be in violation of Eighth Amendment protections against cruel and unusual punishment.

Scholars and advocates, as well as policy makers and correctional officials, increasingly agree that trans people who are incarcerated are differentially exposed to violence while behind bars. Outdated images of predatory homosexuals perpetrating sexual violence and sexually permissive "queens," "wives," or "bitches" engaging in promiscuous prison sex dominated early discussions of prison sexuality and violence but have since been discounted. These images demonized prisoners perceived to be sexually deviant predators and supported policies punishing prison sex. At the end of the 20th century, fear over "homosexuality" in prisons turned to a concern over the safety of gender-nonconforming people who are in prisons.

Trans people, especially trans women of color, have become influential in the prisoner rights movement that prompted prison reform. Most notably, in *Farmer v. Brennan* (1994), the U.S. Supreme Court heighted protections against cruel and unusual punishment because of the brutal beating and rape of Dee Farmer, a Black trans woman incarcerated in Indiana, in the early 1990s. Subsequently, an influential report by Human Rights Watch situated effeminate prisoners within the hypermasculine social structure of men's prisons and found "endemic" assault of the feminine there. This helped pass the 2003 Prison Rape Elimination Act, or PREA, which allotted federal funding to deter prison rape.

Now nearly two decades after PREA, trans women are still more than 13 times more likely to be sexually assaulted than their cis counterparts, which sparks questions about the future of trans prisoners in the face of continuing crisis. Because

prisons continue to differentially inflict "the pains of imprisonment" on trans people, the experiences of trans prisoners shape understandings of corrections and mobilize movements for prison abolition. As a result, incarceration of trans people is a significant issue for future research, advocacy, and change that places trans prisoners as a central issue of concern.

Intellectual and Cognitive Disabilities, People With

Discussions of transgender identities, affirmations, and politics typically rely on, or assume, trans individuals' ability to self-advocate and self-direct. However, people with cognitive and intellectual disabilities do not always have the ability to self-advocate and self-direct. Cognitive disabilities present obstacles to learning or understanding; intellectual disabilities (IDs) are a subset of cognitive disabilities that involve a low intelligence quotient or limit a person's ability to understand, reason, or adapt to new situations. These disabilities present a unique challenge for trans individuals in comprehending and communicating their own identities and in accessing the care and communities they need to thrive.

A Minority Within a Minority

Society at large tends to view people with intellectual and, to a lesser degree, cognitive disabilities as "innocent" or "childish." Such perceptions lead to the assumption that these individuals may not fully understand, let alone experience, their own gender and sexuality. Those who cannot express their gender identity are often assumed to be comfortable with their sex assigned at birth—and those who can may find their experiences dismissed.

This view of people with intellectual or cognitive disabilities as cisgender (cis) and either asexual or heterosexual by default has led to inequalities in this population's right to express and explore their gender identity. Many studies have focused on the marginalization of people with IDs, an effect that is intensified when these individuals identify as LGBTQIA+, and this marginalization may mean that LGBTQIA+ people with IDs cannot access the support resources they need. Barriers to understanding and expressing identities may also lead to internalized transphobia and unwillingness to "come out" or to request support with gender dysphoria. People with IDs who do express a gender identity different from their sex assigned at birth may face opposition from friends, family, and even health care providers.

These effects are not felt to the same degree across different demographics. Older people with IDs are less willing to identify as LGBTQIA+, and those with less access to support—whether due to finances, geographic location, cultural or religious background, or other factors—are less likely to express their identities, seek assistance, and pursue interventions. Studies to date have focused on understanding and describing lived experiences, but more research is needed into potential interventions, their outcomes, and the effects of demographic differences.

Overlapping Obstacles

Gender dysphoria and intellectual disability may manifest in similar ways. For instance, both trans

people and people with IDs may experience barriers to health and social care, have a nonnormative physical appearance, and/or face social ostracism. In addition, research has shown that both populations experience higher-than-average rates of mental and physical illness, have low mood and self-esteem, and are more likely to be victims of stigma or abuse. With such significant symptom overlap, gender dysphoria may go unnoticed in people with IDs.

People with IDs face additional challenges when coming out as trans. For instance, many of these individuals live in social or group housing, which is often segregated by gender—and they may fear losing their homes if they reveal their gender identity. Some may not even be aware of the possibility of coming out, because people with IDs often receive less sexual and gender education than their counterparts without IDs and have less access to safe spaces in which to express and experiment with gender identity. Even for those who openly identify as trans, the supports in place to assist with their intellectual or cognitive deficits may not be equipped to address gender-diverse experiences or the accompanying social and practical challenges.

Identifying and Supporting

Although some research has been done on the intersection of sexual orientation and cognitive and intellectual disabilities, little is known about gender-diverse experiences in people with IDs. Most published research involves case studies of individuals—mostly teenagers and young adults who express a dislike of their sexual characteristics or expected gender roles. In 2010, a study of 27 individuals with developmental disabilities by Cheryl Bedard and colleagues revealed four with gender dysphoria, even though all participants appeared comfortable in their gender identities. Not only does this suggest a potentially higher rate of gender diversity than in the general population, but it also emphasizes the need to be attentive to gender identity in people with IDs.

Importantly, these individuals may find it difficult to express their experiences of gender or may appear to lack a full understanding of gender, whether as a concept or specifically in reference to themselves. This can present a barrier to obtaining appropriate recognition and treatment where applicable, because people with IDs who otherwise meet the criteria for gender dysphoria and transition readiness may not be able to clearly express understanding and consent in the same way as peers without intellectual or cognitive disabilities. Case studies have highlighted the value of an individualized approach to presenting treatment options and obtaining consent from people with ID who wish to transition.

interACT: Advocates for Intersex Youth

interACT: Advocates for Intersex Youth was founded in 2006 under the name Advocates for Informed Choice (AIC) by lawyer Anne Tamar-Mattis, a longtime intersex ally. AIC's mission is to end medically unnecessary surgeries on intersex children, using the law to secure protections for intersex people. Among its accomplishments, the group has educated medical and legal professionals and the general public about intersex experiences, helped develop legislative and policy initiatives to end the medical mistreatment of intersex people, developed the world's largest cohort of intersex youth advocates, and increased intersex visibility in the media.

Intersex is an umbrella term encompassing dozens of variations that cause physical sex characteristics that often transcend typical definitions of male or female bodies. These traits can affect chromosomes, genitals, internal reproductive organs, and hormones. According to biologist Anne Fausto-Sterling, approximately 1.7% of the global population is intersex, and around 1 in 2,000 infants are born with sex characteristics that are visibly different at birth. These infants are at an especially high risk of being subjected to nonconsensual and unnecessary surgeries to "normalize" their bodies.

The surgeries are almost always purely cosmetic, to conform with social assumptions about how bodies should appear. The many risks associated with such operations in childhood include urinary incontinence, an increased risk of urinary tract infections, scarring, chronic pain, infertility, sexual dysfunction, and psychological issues including posttraumatic stress disorder. Follow-up surgeries (with their own accompanying risks) are often required to address complications from the initial surgery.

One of AIC's first programs, Project Integrity, sought to ensure that intersex children would have the same civil rights protections as other individuals and not be subjected to harmful and unwanted medical interventions. In 2012, Tamar-Mattis testified before the United Nations (UN) Special Rapporteur on Torture about the medical abuses experienced by intersex children. The Special Rapporteur released a report the next year calling on states to repeal laws that allowed for nonconsensual medical procedures, including childhood genital-normalizing surgery. Since then, multiple international human rights bodies and U.S.-based LGBTQ+ and medical groups have echoed the call to protect intersex bodily autonomy.

Also in 2012, AIC volunteers formed interACT Youth, a collective of outspoken young intersex people invested in increasing the visibility of the intersex movement. As of 2020, this group has more than 60 members, who engage in various forms of advocacy and awareness raising. In 2016, Advocates for Informed Choice changed its name to interACT: Advocates for Intersex Youth to center the voices and experiences of intersex young people. The organization also grew and changed leadership; it expanded from being a one-person nonprofit to having a youth program director, a communications director, and two full-time attorneys (both former students of Tamar-Mattis's), under a new executive director, Kimberly Zieselman, an intersex woman, lawyer, and the author of *XOXY: A Memoir.*

interACT's work now includes training sessions for medical and legal audiences, social media advocacy campaigns, resource and toolkit development, international human rights consultation, legislative and other policy efforts, and youth leadership development. interACT has trained more than 500 medical professionals; published in medical, legal, and bioethical journals; and presented at numerous health care centers and medical schools. The organization has also provided testimony to multiple United Nations Committees and Special Rapporteurs and worked closely with the UN Office of the High Commissioner for Human Rights. interACT partnered with Human Rights Watch to conduct research on the human rights abuses experienced by intersex children in medical settings in the United States and released a report in 2017 that documented the lived experiences of intersex people, their families, and medical professionals and made various recommendations to policymakers to ensure intersex children are protected. In 2018, interACT worked with California Senator Scott Wiener to pass SCR-110, a resolution that became the first piece of legislation in the United States to acknowledge the medical mistreatment of intersex people. This resolution led to

SB 201, a bill introduced the following year, which aimed to restrict doctors in California from performing medically unnecessary intersex surgeries on children before they are able to give meaningful consent. Despite organizations such as Equality California and the ACLU joining interACT in advocating for the bill, it was strongly opposed by the medical community and did not make it out of committee and died in January 2020.

With the intent of increasing intersex awareness, interACT has become increasingly involved in media projects that seek to represent the intersex community. This work began in 2012 with interACT sponsoring The Interface Project, a digital video initiative led by activist Jim Ambrose that documented the lived experiences of intersex people from around the world. In 2014, interACT consulted with MTV to develop an accurate intersex character for the second season of their teen drama, *Faking It*. interACT youth member Amanda Saenz was cast in the role and became the first intersex person to portray an intersex character on television. In 2015, interACT youth members and former board president Sean Saifa Wall worked with Buzzfeed to create a video, "What It's Like to Be Intersex," that has become a widely used teaching tool. In 2017, interACT partnered with internationally renowned model Hanne Gaby Odielle on her coming out as intersex and advocating for change.

interACT has achieved much since its inception over a decade ago. Intersex young people are more vocal than ever; many youth members are engaging in activism at a more personal level and with greater independence. interACT youth members have presented their work at the HRC's Time to Thrive, the National LGBTQ Task Force's Creating Change, and the Gender Odyssey conferences, and they have advocated for intersex rights in state legislatures and at medical conferences. Such efforts have increased awareness and captured the attention of international human rights institutions and state and local governments in the United States. As a result, societal views of intersex people are changing, which will ultimately end the practice of needlessly operating on healthy intersex children.

International Conference on Transgender Law and Employment Policy

The International Conference on Transgender Law and Employment Policy, also known as ICTLEP and the Transgender Law Conference, was a nonprofit organization founded in 1991 to address the legal rights of trans people, which were largely ignored at the time by local, regional, and national lesbian and gay advocacy groups. ICTLEP held an annual conference in Houston, Texas, for 6 years, from 1992 to 1997. Although it was relatively short-lived, ICTLEP brought much greater attention to trans legal rights, encouraged national lesbian and gay organizations to become more trans inclusive, and educated and empowered many trans people to advocate for change locally and nationally.

Origins

ICTLEP began as a committee of the Gulf Coast Transgender Community and was initiated by Houston lawyer Phyllis Randolph Frye, who was a leader of the group. Frye recognized the need for an advocacy organization for trans rights laws because of her own experiences with discrimination: When she earned her law degree, no firm would hire her because she was trans. Frye sought to build interest in the conference by promoting it at regional and national trans events and by sending a brochure to individuals on the mailing list of the Texas "T" Party, a large, annual trans event held in San Antonio. Still, she discovered that many trans people, especially trans legal professionals, were reluctant to be involved with such a public trans event. Only three trans lawyers—all closeted—attended the first conference, and because she could not find any trans people in the legal field who would be willing to be the main speakers, she asked supportive cis lawyers and judges she knew. However, over 50 people attended, including a number of leading trans activists.

Conference Topics and Resolutions

The areas of law addressed in the first conference were military, housing, probate and civil commitment, insurance, employment, health, antidiscrimination, criminal, and family.

In subsequent conferences, other areas of law were added, including documentation, education, and international, and the legal needs of trans men, trans people of color, and trans individuals in prison. The proceedings of first five conferences were published, enabling the presentations and policy proposals made at the event to be widely circulated beyond those in attendance.

The second ICTLEP was noteworthy for developing and adopting the "International Bill of Gender Rights," a declaration that people of all genders should have 10 basic human rights:

- The right to define gender identity
- The right to free expression of gender identity
- The right to secure and retain employment and to receive just compensation
- The right of access to gendered spaces and to participate in gendered activity
- The right to control and change one's own body
- The right to competent medical and professional care
- The right to freedom from involuntary psychiatric diagnosis and treatment
- The right to sexual expression
- The right to form committed, loving relationships and enter into marital contracts
- The right to conceive, bear, or adopt children; nurture and have custody of children; and exercise parental capacity

The second ICTLEP also first adopted the "Health Law Standards of Care for Transsexualism," a more trans-affirming model than the guidelines then in effect for the medical professionals who worked with trans women and men in the process of transitioning. Both documents were reviewed and revised at subsequent ICTLEPs.

ICTLEP developed different project areas that did work beyond the conferences, which encouraged ongoing engagement and enabled trans people who had not been at ICTLEP to become involved. Some of these projects included Employment Law and Policy, Documentation Law, Gender Rights and Military Law, and the Health Law Project. The conference and its projects provided opportunities for trans activists to meet each other and hone their organizing skills, and a growing number of trans lawyers began to attend ICTLEP, many of whom became inspired to come out and work on the legal rights of trans people. In between conferences, Frye also started sending an email blast that she called the "Phyllabuster" to ICTLEP attendees and other activists to keep them updated on trans legal and political issues—a practice she continued for more than a decade after the conferences ceased.

Legacy

ICTLEP ended after the 1997 event. Frye was having health problems at the time and was burned out from being the primary organizer of six annual conferences. But, more important, it had largely served its usefulness. Influenced by ICTLEP attendees and other trans activists, some national lesbian and gay organizations, most notably the National Center for Lesbian Rights, the National Gay and Lesbian Task Force (now the National LGBTQ Task Force or the Task Force), and the National Lesbian and Gay Law Association (now the National LGBT Bar Association or the LGBT Bar), took on trans legal and political

rights as a central part of their work by the late 1990s. For example, the Task Force's Creating Change conference and the LGBT Bar's Lavender Law conference began to include panels and workshops on trans issues, and the organizations started to have trans people as staff and board members, including Melinda Whiteway, who served as co-chair of the LGBT Bar in 1998, and Shannon Minter, a lead attorney at the National Center for Lesbian Rights, who came out as trans in 1996.

Along with encouraging national lesbian and gay organizations to become more trans inclusive, ICTLEP helped build the trans rights movement by bringing together and training many trans activists on legal issues. Trans people involved with ICTLEP started and were involved in the trans rights group It's Time America, which had chapters in several cities, and the annual National Gender Lobbying Day, which began in 1995. In no small measure, ICTLEP paved the way for the national trans rights organizations that emerged in the 2000s.

International Pronouns Day

International Pronouns Day is an education and advocacy day about pronouns; it occurs on the third Wednesday of October. Founded in 2018 by Shige Sakurai, the event engages prospective allies in respecting others' pronouns, sharing one's own pronouns, and raising understanding about gender liberation, with pronouns and inclusive language as an entry point to building respect, awareness, and greater learning. The campaign is grassroots in nature, with participation from numerous countries, and is also supported by an executive board and volunteer committees.

History and Focus

International Pronouns Day is the first campaign on the topic to gain major international participation and attention. It was preceded by decades of activism and education by numerous advocates around the world, including localized campaigns to raise awareness about pronouns.

The modern practice of going around a circle and sharing one's own name and pronouns in a group setting has existed since at least the late 1990s, particularly among LGBTQIA+ youth activist spaces. Since that time, cultural practices around pronoun awareness have expanded into many more spaces and communities.

In 2018, after publishing MyPronouns.org, a website about personal pronouns and inclusive language, and involvement with a localized advocacy day on pronouns, Shige Sakurai suggested a larger collaborative day of action and formed an executive board to give direction and support the development of International Pronouns Day. The inaugural board was co-chaired by Sakurai and by Genny Beemyn, both trans activists and higher education professionals working in LGBTQIA+ campus centers in the United States.

While the initial campaign's formulation focuses on pronouns, the campaign website also encourages grassroots participation and localized adaptations of the campaign to various languages and contexts, as desired. Adaptations could include a focus on inclusive language rather than just pronouns, depending on local needs.

Furthermore, the campaign leaders assert that discussing pronouns is meant as an entry point into respectful dialogue with and about trans communities and acknowledges that intersectional social justice requires efforts around racial justice, multilingualism, antiviolence work, restroom access,

health care, and beyond. The campaign seeks to open up some of these conversations through the lens of respecting basic human dignity by referring to people by their correct names and pronouns.

Participation and Results

International Pronouns Day received official registrations and endorsements from more than two dozen countries in all continents except Antarctica. During International Pronouns Day in 2019, Twitter listed "#pronounsday" as the number one globally trending hashtag. Campaign organizers reported 500 million as the estimated potential impressions of the hashtag on social media.

Endorsements and participation came from hundreds of businesses and organizations, such as Rwanda Gender Pride, TransgenderIndia.com, Reason Beer, Pride at Work AFL-CIO, Doula Canada, BlackTransConnection, and the Unitarian Universalist Association.

In addition to an expansive social media impact, the grassroots nature of the event encouraged local organizers to produce their own events and initiatives. Some examples have included an art exhibit in the Netherlands; numerous colleges that organized pronoun cookie decorating or "Pronouns and Pizza" discussion events; a formal proclamation recognizing the day, issued by the mayor of Ithaca, New York; a photos and testimonials series developed by a youth organization in Slovenia; and a short documentary video produced in England. Other local groups conducted workshops, film screenings, outreach, or button making in order to raise awareness and build more supportive communities.

Some local governments and officials also voiced support or announced trans inclusion initiatives on International Pronouns Day, such as acknowledgments of the day from the New York City Mayor's Office, and an announcement from the City of Philadelphia, which said that the city would begin a campaign to include pronouns in city communications and in email signatures of the city's employees.

Media and Recognition

International Pronouns Day has been acknowledged by celebrities on Twitter, such as nonbinary actor Asia Kate Dillon and nonbinary musician Sam Smith. Additional celebrities, such as Alyssa Milano and George Takei, also posted during the event. The campaign hashtag was used by a number of politicians running for president of the United States, resulting in an article about politicians sharing their pronouns published by *The Hill*.

Publishers of several major dictionaries, including the *Oxford English Dictionary* and the *Merriam-Webster Dictionary,* posted tweets for International Pronouns Day. Additional social media posts came from high-profile organizations and companies such as the Human Rights Campaign, Lambda Legal, American Civil Liberties Union, Penguin Random House, and *Entertainment Weekly*. The news-based television channel CNN also published an explainer piece about pronouns in recognition of the campaign. In January 2019, International Pronouns Day received a Special Recognition Award from the Consortium of Higher Education LGBT Resource Professionals in conjunction with the National LGBTQ Task Force's Creating Change conference.

Public Criticism

International Pronouns Day has been publicly criticized by numerous individuals on social media, and the campaign was lambasted by well-known conservative commentators, including Glenn Beck in the United States and Katie Hopkins in the United Kingdom. International Pronouns Day has been mentioned in conservative-leaning media such as *Fox and Friends, The Daily Mail, The Conservative Woman, Weekend Australian, American Thinker, Blaze Media, PJ Media,* and *Daily Caller*.

The vast majority of the criticism of International Pronouns Day has been of an anti-trans nature, often relying on a presumption of prejudice among audiences by focusing on sarcasm and jokes. When more clear critiques have been presented, they have tended to assert language tyranny and liberal indoctrination, that trans people are insane, that bodies determine gender, that bodies/genders are binary, that people will be punished for using the wrong pronouns, that the issue lacks importance, or that supporting the campaign is a waste of energy and resources.

Future Directions

International Pronouns Day leaders have encouraged and stated a vision for further expansion of the campaign by supporting grassroots volunteers working in a greater diversity of world regions and languages. Such engagements may require different entry points than pronouns, depending on the language. Furthermore, leaders have pointed toward the longer-term needs and practices that must be engaged at all times, not just on one annual day of action, in order to ensure that gender-inclusive language and human dignity in communications are adopted as a structural change and not just an individual behavioral change.

International Transgender Day of Visibility

The International Transgender Day of Visibility (TDOV) is held annually on March 31 to celebrate trans people and raise awareness of trans communities worldwide. It was developed, in part, as a reaction to the International Transgender Day of Remembrance (TDOR), which honors trans individuals who have been murdered because of their gender identity. Activists wanted to have a day that would encourage trans pride and call attention to the contributions of trans people to society, rather than the focus being only on the horrific level of violence against trans people. While the TDOV is less well known and less widely commemorated than the TDOR, the number of cities and countries that hold TDOV events continues to grow each year, as communities recognize the importance of having a day that acknowledges the lives of trans people.

The TDOV was created in 2009 by Rachel Crandall-Crocker, a psychotherapist and the executive director of Transgender Michigan in the United States. She began posting about the need for a day to celebrate trans people on Facebook, and the idea was quickly embraced by other trans activists. Crandall-Crocker began contacting trans leaders throughout the United States and internationally to encourage them to support the TDOV, and plans began almost immediately for events to take place in a number of localities. The first TDOV event was held in Royal Oak, Michigan, and consisted of a panel of trans allies discussing how they have supported the trans community. In subsequent years, the event has featured an open mic.

LGBTQIA+ and trans groups in other U.S. cities have organized workshops, films, art projects, ribbon campaigns, coffeehouses, networking activities, and rallies for the TDOV. For example, the TGI Network of Rhode Island sponsors an annual Empowerment Breakfast to honor the occasion; the Long Beach, California, LGBTQ Center runs a "Just Be Trans" Festival; and San Francisco LGBTQIA+ and trans organizations hold a TDOV awards night. The Wells Fargo building in Charlotte, North Carolina, and the One World Trade Center in New York City were lit up in the colors of the trans pride flag to mark the day in 2016 and 2017, respectively. Many national LGBTQIA+ organizations in the United States, including the Human Rights Campaign, PFLAG, GLSEN, and Trans Student Educational Resources, now support and help publicize the TDOV.

More than a decade since it began, the TDOV has grown to be celebrated in numerous countries, including Uganda, Vietnam, France, Ireland, Germany, and Russia. For example, the mayors of the Canadian cities of Calgary and Edmonton issued formal proclamations in 2013 to recognize the day. In 2014, Irish trans activists marked the TDOV by holding a demonstration outside the offices of the

country's national broadcaster to protest the negative representations of trans people on its television shows and in other media. The following year, trans people around the world, particularly trans youth, posted selfies on social media sites to raise awareness and help humanize trans people. Posting to social media continues to be a way that many trans youth celebrate the day annually, and for some, it is the first time that they come out publicly.

But not all trans activists have been supportive of the TDOV. A few days before the event in 2019, long-time trans rights activist Miss Major tweeted, "I don't really understand why we need a Day of Visibility, since for most of us, especially Black girls, we are as visible as we need to be. Our visibility is getting us killed. . . . The people who care about us . . . they're the people who need to become more visible." While there can be no denying that trans women of color are disproportionately targeted for violence and harassment because of the intersecting oppressions of racism, misogyny, and the hatred of trans people and that cis allies need to do much more to address the situation, this type of criticism misses the need for a day to celebrate trans people and encourage them to feel greater pride in themselves. At the same time that trans people are being murdered much more than other groups, they are also killing and attempting to kill themselves at a horrendously high rate because of internalized oppression. The TDOV can help build self-esteem and well-being among trans people, as well as educate the larger society about anti-trans discrimination, and thus the event serves important purposes.

For many trans people around the world, the TDOV is the one day a year that they feel recognized by others and encouraged to celebrate themselves. Even if they are not comfortable being out or live in a country where trans people have few rights or are persecuted, they can be heartened that trans people and their experiences are being spotlighted, even if only for a day. Having events like the TDOV can help lead to changes in society, such that trans people can be visible every day without having to face harassment and discrimination.

Intersectionality in Research

Intersectionality is a concept or perspective that considers the simultaneous manifestation or influence of multiple dimensions of identity, difference, and inequality. The use of intersectionality as an analytical framework in the humanities and social sciences has increased drastically in the past two decades. Much scholarship focused on trans people centralizes the roles of cissexism or transphobia. Given this critical sensitivity to privilege and oppression, scholars engaging in research focused on trans issues may find that several of intersectionality's core assumptions resonate with their own. Furthermore, adopting an intersectional lens in research with trans people will allow scholars to add nuance and depth to what is already known about manifestations and consequences of cissexism.

The purpose of this entry is to serve as a primer for scholars who would like to incorporate intersectionality into research focused on trans people. The entry begins with a brief history of intersectionality, with particular attention devoted to its roots in the thought and praxis of (primarily cisgender [cis]) women of color. Next, the entry describes various approaches to using intersectionality in research. Moreover, examples are offered

that illustrate how these approaches may be employed in research on cissexism.

Intersectionality: A Brief History

Even before it had a name, intersectionality had a long history. In 1851, the renowned abolitionist and women's rights activist Sojourner Truth delivered her famous "Ain't I a Woman?" speech to an audience at a women's rights convention in Akron, Ohio. With this speech, Truth succinctly and incisively articulated how abolishing slavery—and thus freeing African American women—was core to the mission of pursuing rights for women. Other Black women scholar-activists who worked at the end of the 19th century and early 20th century—such as Anna Julia Cooper and Ida B. Wells-Barnett—also described the influence of multiple systems of oppression, such as racism, sexism, and classism, in the lives of Black women, their families, and communities. However, because of the very systems of inequality they critiqued, their intellectual insights were often deemphasized or obscured from history—that is, until their works were revived and popularized in the 1970s and 1980s by a new generation of Black women scholar-activists, such as bell hooks, Angela Davis, Audre Lorde, and the Combahee River Collective. As with their intellectual predecessors, this generation of scholar-activists drew from their lived experiences to describe the co-occurrence and interdependence of systems of oppression. This central thesis was at odds with the dominant ideology and praxis of prominent civil rights organizations at the time, which resisted challenging more than one axis of domination at a time. That is, Black women were often pressured to combat racism *or* sexism (*or* classism, *or* heterosexism, etc.) rather than racism *and* sexism.

The coining of the term *intersectionality* is usually attributed to Black feminist legal scholar Kimberlé Crenshaw, who critiqued the inability of critical race theory or feminist legal scholarship to adequately consider the influence of racism and sexism in the lives of Black women. She used the metaphor of a traffic intersection to illustrate how the discrimination Black women experienced (framed as a car accident) could result from cars coming from one direction (e.g., racism), from another (e.g., sexism), or all of them (e.g., racism and sexism and classism). Thus, the discrimination Black women experience may stem from racism and largely overlap with Black men's experiences of racism. Alternatively, the discrimination Black women experience may stem from sexism and closely resemble the sexism encountered by white women. Importantly, however, Black women could also experience discrimination specifically because they are *Black women*—that is, their mistreatment is not simply the sum of racism and sexism but something qualitatively different and unique to them.

Another important milestone in the development of intersectional thought was sociologist Patricia Hill Collins's description of intersectionality as a structural matrix of domination. Multiple systems of privilege and oppression intersect in this matrix and are co-constituted or mutually influenced by each other. Drawing from this insight, one could consider, for example, the ways that police mistreatment of trans women of color who engage in sex work reflect not just cissexist bias but also sexist, heterosexist, racist, and classist ideas of womanhood, sexuality, criminality, and legitimate work.

Approaches to Intersectional Research

Researchers concerned with the impact of cissexism or transphobia in the lives of trans people may find that intersectionality's emphasis on systems of privilege and oppression resonates with their own analytic goals. Moreover, incorporating an intersectional lens may help scholars glean new insights into factors that shape the manifestation or consequences of cissexism in diverse trans people's lives. To aid scholars who wish to incorporate intersectionality into their work, various approaches to intersectional analysis—comparative, additive, interactional, and intersectional—previously articulated by Jioni Lewis and Patrick Grzanka in their discussion of incorporating intersectionality in research on racism—are described. When possible, examples of both quantitative and qualitative research designs are presented. Such examples represent only a few ways that researchers may draw from intersectionality to add nuance and depth to scholarship that centralizes the perspectives of trans people.

Comparative Approach

Cissexism research employing the comparative approach would assess how cissexism manifests in

at least two groups of trans people who differ on some dimension of identity other than gender identity, such as race. Thus, researchers could explore whether the cissexism experienced by white or European American trans people differs in level (in quantitative designs) or kind (in qualitative designs) from the cissexism experienced by Asian American trans people. Alternatively, researchers using quantitative designs could explore if the association of cissexism with some outcome variable (e.g., self-esteem) varies across the two groups of trans people. A benefit of this approach is that by uncovering within-group variability in a phenomenon, researchers can avoid perpetuating the specious claim that the subjective experience of one group of trans people (usually, the one with more sociocultural privilege) is universal. A weakness of this approach is that it usually provides no information regarding the source of observed differences between groups. Using the aforementioned example, if any difference between the two groups was observed, researchers would likely assume the cause of this difference was racist discrimination (or, conversely, white privilege). Often, however, this presumed cause is not measured in research that adopts comparative designs. Another limitation of the comparative approach is that it may tacitly perpetuate the belief that research on groups with multiple marginalized identities (e.g., Asian American trans people) is not worthwhile in and of itself but rather only inasmuch as it reveals something about groups with more sociocultural privilege (e.g., white/European American trans people).

Additive Approach

Research using the additive approach assesses participants' experiences of multiple forms of oppression independently. The additive approach can be used in both qualitative and quantitative designs. For example, a researcher collecting qualitative interview data may ask trans women to first describe their experiences of workplace sexual harassment and then to describe their experiences of workplace cissexist harassment. Subsequently, the researcher would analyze participants' responses to the two questions separately to understand the different ways that sexism and cissexism manifest for trans women in the workplace. Alternatively, a researcher could collect quantitative survey data on trans women's experiences of workplace sexual harassment and workplace cissexist harassment—assessed separately—and examine their unique associations with participants' job satisfaction. A strength of an additive research design is that it reflects the understanding that people can experience multiple forms of oppression simultaneously. Furthermore, unlike the comparative approach, the additive approach can be performed using within-group research designs (e.g., the entire sample being trans women), which affirms the value of studying groups on their own merit rather than in relation to another group that is implied to be "the norm." Nonetheless, additive approaches assume that multiple forms of oppression can be perceived or experienced separately. Using our examples, the use of separate interview questions or survey instruments to measure workplace sexual harassment and workplace cissexist harassment assumes that trans women only experience workplace harassment because they are women *or* because they are trans; it does not allow for the possibility that they experience harassment specifically because they are *trans women*. Moreover, additive approaches are less likely to explore the dependent, co-constitutive nature of multiple forms of oppression. Thus, using our examples, researchers who assess workplace sexual harassment and workplace cissexist harassment separately may not consider the ways that cissexism is itself bolstered by the same binary, reductionist notions of sex and gender that have historically served as the foundation of sexist ideology.

Interactional Approach

As with the additive approach, the interactional approach assesses multiple forms of oppression simultaneously but independently. However, research adopting an interactional approach—which almost exclusively uses quantitative designs—assumes that the association of one form of oppression with an outcome variable is strengthened by another form of oppression. Thus, for example, scholars may develop a survey that separately assesses undocumented immigrant trans people's experiences of cissexist discrimination and xenophobic or nativist discrimination. Subsequently, the scholars would calculate the statistical interaction of cissexist discrimination with nativist discrimination and examine the

interaction's association with some outcome variable, such as income. As with the additive approach, a strength of the interactional approach is that it acknowledges that people can experience multiple forms of oppression simultaneously. Moreover, the interactional approach also allows for the possibility that these forms of oppression can work together—sometimes in complex ways—to shape people's experiences and functioning. Nonetheless, as with the additive approach, the interactional approach assumes that people always experience multiple forms of oppression as discrete, separate phenomena.

Intersectional Approach

Jioni Lewis and Patrick Grzanka label the fourth and final way of engaging in intersectional research the intersectional approach—a pointed designation that reflects their understanding that this approach most fully engages with the core themes of intersectionality. Stated plainly, researchers using the intersectional approach assume that the co-occurrence of forms of oppression can produce experiences that are unique to the population occupying that specific social location. Consider the case of a trans man who lives in poverty because he was fired from his job after coming out to his employer (there is no federal law banning employment discrimination on the basis of gender identity or expression). After losing his job, he no longer has access to the hormone replacement therapy he received through his employer-sponsored health insurance plan. Moreover, his state Medicaid program does not cover transition-related health care, which leaves him with the choices of going without his medically necessary treatment; moving to a state that does provide such coverage, which would be expensive; or seeking reduced-cost (but potentially unregulated and unsafe) hormone replacement therapy through the underground economy. In this situation, classist or capitalist health care policies exacerbated a health care crisis precipitated by a lack of legal protections against gender identity–related discrimination. Moreover, the fact that some state Medicaid programs do not cover trans-affirmative health care itself reflects classist and cissexist notions of what health care working-class trans people and trans people living in poverty have the right to access.

Given the nuanced, complex nature of the interplay of multiple forms of oppression, some scholars suggest that qualitative research methods—which tend to be less hypothesis driven and prioritize the subjective experiences of participants—are more aligned with the intersectional approach. Continuing the example above, researchers employing qualitative designs may ask participants to describe in their own words the discrimination they encounter as trans people living in poverty. Analysis of the data collected could reveal categories or themes that overlap with prior conceptualizations of classism and cissexism or they could illustrate experiences that clearly reflect the intersections of oppressions (e.g., classist cissexism or cissexist classism). Subsequently, researchers may use mixed-method or quantitative designs to develop and validate a self-report instrument of participants' experiences of classist cissexism.

Intersex Society of North America

The Intersex Society of North America (ISNA) was a nonprofit organization founded in 1993 in San Francisco, California, by intersex activist Cheryl Chase (also known as Bo Laurent). It was formed to provide peer support to intersex people, to educate family and friends, and to advocate for changes in the medical practices imposed on intersex infants. ISNA was the world's largest intersex organization in the 1990s and played an important role in the U.S. intersex rights movement. The organization had approximately 3,500 members, many of whom were educated, white, middle-class people between the ages of 30 and 45. Most were from the United States and Canada, but some resided in the United Kingdom, Germany, and New Zealand.

In the 1990s, discussions surrounding intersexuality started to grow, as scholars included the topic in sex and gender research. Biologist Anne Fausto-Sterling, in particular, published scholarship that challenged the common understanding that sex was a simple dichotomy. In her article, "The Five Sexes: Why Male and Female Are Not Enough," she argued that there are five types of sexes: males, females, true hermaphrodite ("herms"), male pseudo-hermaphrodite ("merms"), and female pseudo-hermaphrodite ("ferms").

After reading Fausto-Sterling's work, Chase penned a response to critique the use of *hermaphrodite* and the concept of gonadal determinism, which served as the basis for sex reassignments on intersex bodies. She also shared her personal story about being one of many intersex people who had been subjected to harmful medical interventions to "correct" their genitals. When the letter was published, Chase received an outpouring of responses from other intersex people who wanted to share their stories. In the letter, Chase had claimed that she was affiliated with the Intersex Society of North America to give herself credibility; the organization did not actually exist. But the tremendous support for her letter led Chase to actually establish ISNA because it was clear that there was a need for such a community.

Intersex people started joining ISNA as they realized that they all had been mistreated by medical practitioners. The members committed to advocate for intersex rights because they did not want additional intersex children to be subjected to the harmful surgeries that they had endured. Their activism came in the form of aggressively criticizing the Optimal Gender of Rearing (OGR) model (a protocol used for intersex babies, in which they were assigned a gender and then their genitals were surgically modified to match that gender), combating shame and stigma, encouraging other intersex people to embrace their bodies as natural and beautiful as they are, and ending irreversible and unnecessary surgeries. To further their agenda, they strategically used confrontational protests, media and online critiques, and in-person dialogues.

With the rise of the Internet, ISNA grew as a community online. Allies also increased in the academy, as scholars in medicine, law, feminism, and the media used their platforms to critique the OGR model and highlight how intersex children were treated in extremely harmful and dehumanizing ways. Despite medical professionals' initial resistance toward the critiques and calls for change, they began to listen and reconsider their practices in the early 2000s. This was partly due to ISNA activists routinely protesting pediatric medical association meetings and allies applying pressure to the physicians to provide data that supported the use of the OGR model. As a result, clinicians began to show interest in reforming medical practices on intersex bodies and moving away from the sex reassignment approach.

In 2000, at the Lawson Wilkins Pediatric Endocrine Society meeting, Chase was invited to give a talk on the mistreatment of intersex bodies. It was one of the first instances in which doctors were willing to collaborate with intersex people and listen to what they had to say. Chase continued to collaborate with doctors, and in 2005, she was invited to a conference where various international intersex experts were conceptualizing a new medical protocol for intersex treatment called the "Consensus Statement

on Management of Intersex Disorders." She pushed for *intersex* to be replaced with *disorders of sex development* (DSD) as a way to appeal to doctors with terms that they could easily accept and use when discussing intersex bodies. Chase also no longer wanted *hermaphrodite, true,* or *pseudo* to be descriptors for anatomical differences.

Also in 2005, the Consortium on the Management of Disorder of Sex Development (DSD Consortium), a group of intersex people, parents of intersex children, and clinicians who were affiliated with ISNA, drafted guidelines for doctors that were an alternative to the OGR model and created a handbook for parents. The guidelines listed ways that patient-centered care should focus on the well-being of intersex people and provided recommendations for physicians who treat intersex patients. Along with the handbook, which was distributed to medical centers around the United States, these new standards led additional practitioners to shift their perspective on intersex management.

The recommendations in the "Consensus Statement" drew mixed reactions from intersex activists when they were published in 2006. In addition to introducing the language of "disorders of sex development," the document advocated for a multidisciplinary team of experts to treat intersex variations, the limited use of surgeries for cosmetic purposes, and approaches to diagnosing intersex variations in infants. Many ISNA members were displeased with the recommendations, especially with the new DSD nomenclature, because they did not see their bodies as disordered. This added to their frustrations over the direction in which the organization was heading. Some members were in favor of collaborating with physicians, while others wanted to go back to a more radical approach of confronting medical professionals. Because of these internal conflicts, ISNA disbanded in 2008.

Although the organization was relatively short-lived, ISNA helped pave the way for intersex rights during the 1990s and early 2000s. The members mobilized to eradicate unnecessary surgeries, spread awareness, and create a supportive space for intersex people. After employing protest strategies, ISNA was able to work with medical professionals to conceptualize new practices for treating intersex bodies.

INTERSEXUALITY

Aside from male and female, humans are also born intersex. Approximately 1 in 2,000 live births results in anatomies with both traditionally male and female sex characteristics, such as genitals, hormones, chromosomes, and gonads. Intersexuality threatens the longstanding sex binary model and causes anxiety among physicians, who cannot easily categorize them. Medical interventions routinely occur to "normalize" atypical bodies, despite opposition from intersex activists since the 1990s. An increase in intersex awareness has broadened discourses about bodily autonomy, representation, and recognition, and intersexuality continues to expand the concept of sex in the 21st century. This entry begins with definitions of key terms that occur within the discourse of intersexuality, then continues with an extended discussion of the process of medicalization that led, in the second half of the 20th century, to the performance of surgeries on many intersex infants, with the aim of assigning either male or female sex in keeping with the societal norm of binary sexuality and often entailing further confirmatory surgeries and procedures as the child grew older. Next, the rise of the intersex rights movement in the 1980s and 1990s is

described and its accomplishments outlined. The entry concludes with a discussion of the recognition of nonbinary sexuality and the rising number of bans in U.S. states on the performance of medically unnecessary intersex surgeries.

Definitions

Hermaphrodite and Hermaphroditism

A *hermaphrodite* is defined as an individual who is biologically both male and female, taken from Hermaphroditus, a figure in Greek mythology who was a combination of a man and a woman. Although the word is largely seen as a pejorative today, *hermaphrodite* was once commonly used to describe bodies that do not neatly fit into the male or female sex category. This term is rooted in pathologist Theodor Albrecht Edwin Klebs's classification of hermaphroditism: "true hermaphrodite," "male pseudo-hermaphrodite," and "female pseudo-hermaphrodite." Sex during the 19th century was primarily identifiable through the tissue structure of the gonads (ovaries/testes), and Klebs identified these categories in the late 1870s to acknowledge the rarity of a combination of ovarian and testicular tissue in the same body. Klebs specifically claimed that true hermaphrodites have one ovary and one testis; female pseudo-hermaphrodites have all of the "standard" male genitalia but ovaries, not testes; and male pseudo-hermaphrodites have all of the "standard" female genitalia but testes, not ovaries.

In contemporary times, many people who have a mixture of female and male sex traits reject the term *hermaphrodite* because it is used in a disparaging manner to describe their bodies. Their anatomical differences are viewed as abhorrent, inferior, and abnormal because they do not neatly fit into the two-sex model. Since the 1990s, some intersex activists have referred to themselves as "hermaphrodites" as a protest strategy and as a way to reclaim power and authority over their bodies, similar to how "queer" and "dyke" have been reclaimed by LGB people.

Intersex and Intersexuality

Intersex is an umbrella term used to describe a range of diverse variations in sex that include both traditionally male and female attributes. Coined by geneticist Richard Goldschmidt in the early 1900s to categorize gypsy moths with atypical sex characteristics, the term *intersex* began to replace *hermaphrodite* in the 1940s at the urging of physician Alexander Polycleitos Cawadias, who believed that all humans fall somewhere between male and female. Intersex is often conflated with *ambiguous genitalia,* a condition in which someone's body cannot be readily identified as traditionally male or female, such as an individual with a smaller-than-typical penis. However, intersex bodies can have a combination of traditionally male and female sex traits that are external and/or internal, including genitals (penis/vagina), chromosomes (XY/XX), hormones (estrogens/androgens), and gonads (testes/ovaries). *Intersex* is used by many activists and community members because it is a term that is all-encompassing of the approximately 20 variations of atypical sex characteristics. Therefore, for the remainder of this entry, the term *intersex* will be used.

Disorders/Differences of Sex Development

Individuals with *disorders of sex development* (DSD) have bodies with congenital conditions that are a result of atypical development of hormonal, chromosomal, genital, and gonadal sex. The term *DSD* was introduced in 2005 by physicians who wanted a more medically accurate description of intersex variations that could be used with patients and their families. In 2006, DSD was listed in the "Consensus Statement on Management of Intersex Disorders" as part of new standards of care for intersex people. This new language elicited a range of responses from scholars, activists, and community members. Some were in support of the shift because it was a pragmatic approach to work directly with medical professionals, while others denounced the new terminology on the grounds that referring to anatomical variations as "disorders" is intrinsically pathologizing. Many intersex activists see the use of the term *DSD* as another way for physicians to reassert their power over intersex bodies. As compromise language, some have adopted the term *differences of sex development* because this phrase does not have the judgmental overtones of "disorders" and recognizes intersex bodies as natural sex variations.

Medicalization

The leading medical authority on intersex variations in the second half of the 20th century was John Money, a professor of pediatrics and psychology at Johns Hopkins University from 1951 until his death in 2006. His research focused on gender and sexual identity and nomenclature, and he helped develop the Johns Hopkins Gender Identity Clinic, which was the first university gender clinic established to perform gender-affirming surgeries. Money believed that all people were psychosexually neutral at birth and developed a sense of their gender between the ages of 18 months and 3 years through socialization by their families. This concept became known as the Optimum Gender of Rearing (OGR) model and was used as a justification for performing binary sex assignment surgeries on infants born with ambiguous genitalia, as well as on young children who had experienced trauma to their genitals.

Although the OGR model posited that young children did not have a gender identity, most of the surgeries resulted in female sex assignments. Because attention was largely placed on the (heterosexual) functionality and overall aesthetics of the genitals, Money and his colleagues found it easier to construct a vagina than an average-sized penis. For doctors to successfully construct functioning penises, the phalluses needed to be capable of urination, erection, and ejaculation. Vaginas, however, were considered successfully functional if they just had a large enough hole to fit a penis inside and the outward appearance resembled a "standard" vagina. Thus, the common practice for decades beginning in the 1960s was to give vaginas and a female sex assignment to most infants with ambiguous-looking genitalia, resulting in thousands of surgeries.

In what became his most famous case, Money applied his OGR theory to David (né Bruce) Reimer, an identical twin boy from Winnipeg, Canada, who experienced a botched circumcision in 1966. The 8-month-old suffered irreparable damage to his penis due to the physician's having used an unconventional method of removing his foreskin. Shortly after the tragic mishap, Reimer's parents began working with Money to surgically reconstruct the child's genitals. Citing the OGR model, Money convinced the parents that it was in their child's best interest to be raised as female, because it was easier to create a vagina than a penis, and the child was supposedly still young enough to be socialized to the appropriate gender, as long as it was never disclosed to the child that they had been assigned male at birth.

Money performed annual checkups to follow Reimer's progress through childhood and adolescence and used his twin brother Brian as a control subject, often requiring them to interact together in so-called childhood sexual play. Money declared what he called the John/Joan case a success in numerous articles, books, and presentations because, as he reported, Reimer exhibited traditionally girlish behavior in comparison to his brother's traditionally boyish behavior. Given that this was the first known case of someone who was unquestionably one sex being reassigned to another sex with seemingly no difficulties provided strong evidence for Money's model.

But other scholars, including sexologist Milton Diamond, who did not believe that gender identity in young children was entirely malleable, were not convinced that Money was telling the full story. Diamond tracked down Reimer in the mid-1990s and learned that he had self-identified as male since childhood and only acted as traditionally female to appease his parents and Money. After learning about his sex reassignment from his father when he was 14 years old, Reimer decided to transition back to a male sex. He changed his name to David, received testosterone therapy, and underwent surgeries to remove his breasts and reconstruct a penis.

The publication of Diamond's findings and coverage of Reimer's story in the media in the late 1990s discredited Money's theory that gender is not in place at birth but determined by socialization and called into question the rationale for performing genital surgeries on intersex infants. Money's reputation and his views about childhood gender identity were further damaged after both Reimer brothers took their own lives: Brian in 2002 and David in 2004.

Medical Interventions on Intersex Bodies

Prior to his malpractice being exposed, Money used the John/Joan case to encourage physicians to perform genital surgeries on babies born with

intersex variations, and doctors readily bought into the OGR model because they believed that "unintelligible" bodies needed to be corrected. Like Money, other medical professionals sought to provide what they considered a normative psychosocial developmental experience to intersex infants by choosing a gender identity for them and then modifying their genitals accordingly. These "corrective" surgeries became the standard response to bodies that did not neatly fit into the male or female sex category.

Physicians sought to have control over anatomically different bodies because they wanted to maintain the binary systems of sex and gender. Given the fundamental threat that the existence of sex variations posed to the social structures that separated bodies into two distinct categories, the medical discipline had to respond. Thus, physicians defined intersexuality as a medical problem that only they could address, which was through binary sex assignment surgeries. They essentially attempted to erase intersex bodies and reproduce male and female sexual anatomies.

Parents of intersex children were also often involved in the medical management of intersex bodies by cooperating with physicians. Genital surgeries were sometimes performed without notifying the child's parents, but in most cases, physicians pressured the parents to allow them to intervene. The nature of the intersex variation was typically presented as a medical emergency, in which the child was said to have a disorder or illness that resulted in their sex not being easily identifiable. Binary sex assignment was then given as the remedy to the problem and the best course of action for the sake of the child and the family. This decision was made either immediately after delivery or during early childhood, based on the assumption that the child would not remember the procedure and that they could be socialized to the given gender, per the OGR model.

The children experienced different genital surgeries, depending on their chosen sex and the intersex variation. Children whom doctors considered to have an adequately sized penis were assigned male and underwent repairs to their penis during the first year of their lives and had additional surgery before starting school. All other children were assigned female and had surgery around the age of 3 months to construct or repair a vulva and to create or sometimes reduce the size of a clitoris. Additionally, vaginoplasty (a procedure to tighten the vagina) occurred between the ages of 1 and 4, and the construction of a complete vaginal canal was performed during puberty. Hormone therapy to further align their bodies with the stereotypical characteristics of their assigned sex occurred during adolescence for both males and females.

Because binary sex assignment required years of reconstructive surgeries, the consequences for those who underwent the procedures were severe and lifelong, affecting their physical, psychological, and emotional well-being. The decision to irreversibly alter the children's bodies to conform to the dominant sexed categories was determined by doctors and parents without their consent, which resulted in many intersex people feeling that they had been violated when they later learned what had happened to them. The surgeries were seen as "in the best interest of the child," even though the procedures were mostly medically unnecessary and cosmetic in nature, and the child was typically not told at the time about their intersex variation and what was to be done to their bodies. And, while the aim was to create "natural-looking" bodies, the genitals did not always look that way due to scar tissue, disfigurement, issues resulting from frequent infections, and other medical conditions. The surgeries also caused sterilization in bodies that had been capable of reproducing children prior to medical intervention.

Parents hid the truth about the procedures from their children because they were following doctors' orders to remain silent and because they were afraid of what other people would think, say, or do out of ignorance and cruelty. For their part, physicians required secrecy because they were firmly committed to Money's theory on gender socialization and to the sex binarism of Western societies. The medicalization and secrecy about their bodies resulted in the adults who had been born with an intersex variation feeling ashamed and stigmatized.

The Intersex Rights Movement

In the late 1980s and early 1990s, questions increasingly were raised about the effectiveness and ethics of binary sex assignment surgeries. Intersex adults were among the people who openly condemned the treatment of intersex bodies by

physicians. Many of them united to share their traumatizing experiences, increase awareness of the harmful effects of medical interventions, and confront the medical establishment. As more intersex adults learned that there were other people in the world like themselves, the intersex community began to grow. This led to the formation of intersex organizations and encouraged many intersex people to become activists and speak out in newspaper articles, television shows, and the meetings of medical professionals.

The advent of the Internet made it much easier for intersex people to find each other, receive support, and obtain detailed information about their intersex variations. Online intersex communities provided a safe space in which they could ask questions about where to find resources, how to cope with being intersex, and what was done to their bodies. Some even discovered their intersexuality from websites that described particular anatomical differences. This was a major shift for people who had spent much of their lives living silently in shame, confusion, and fear.
